gcc -help

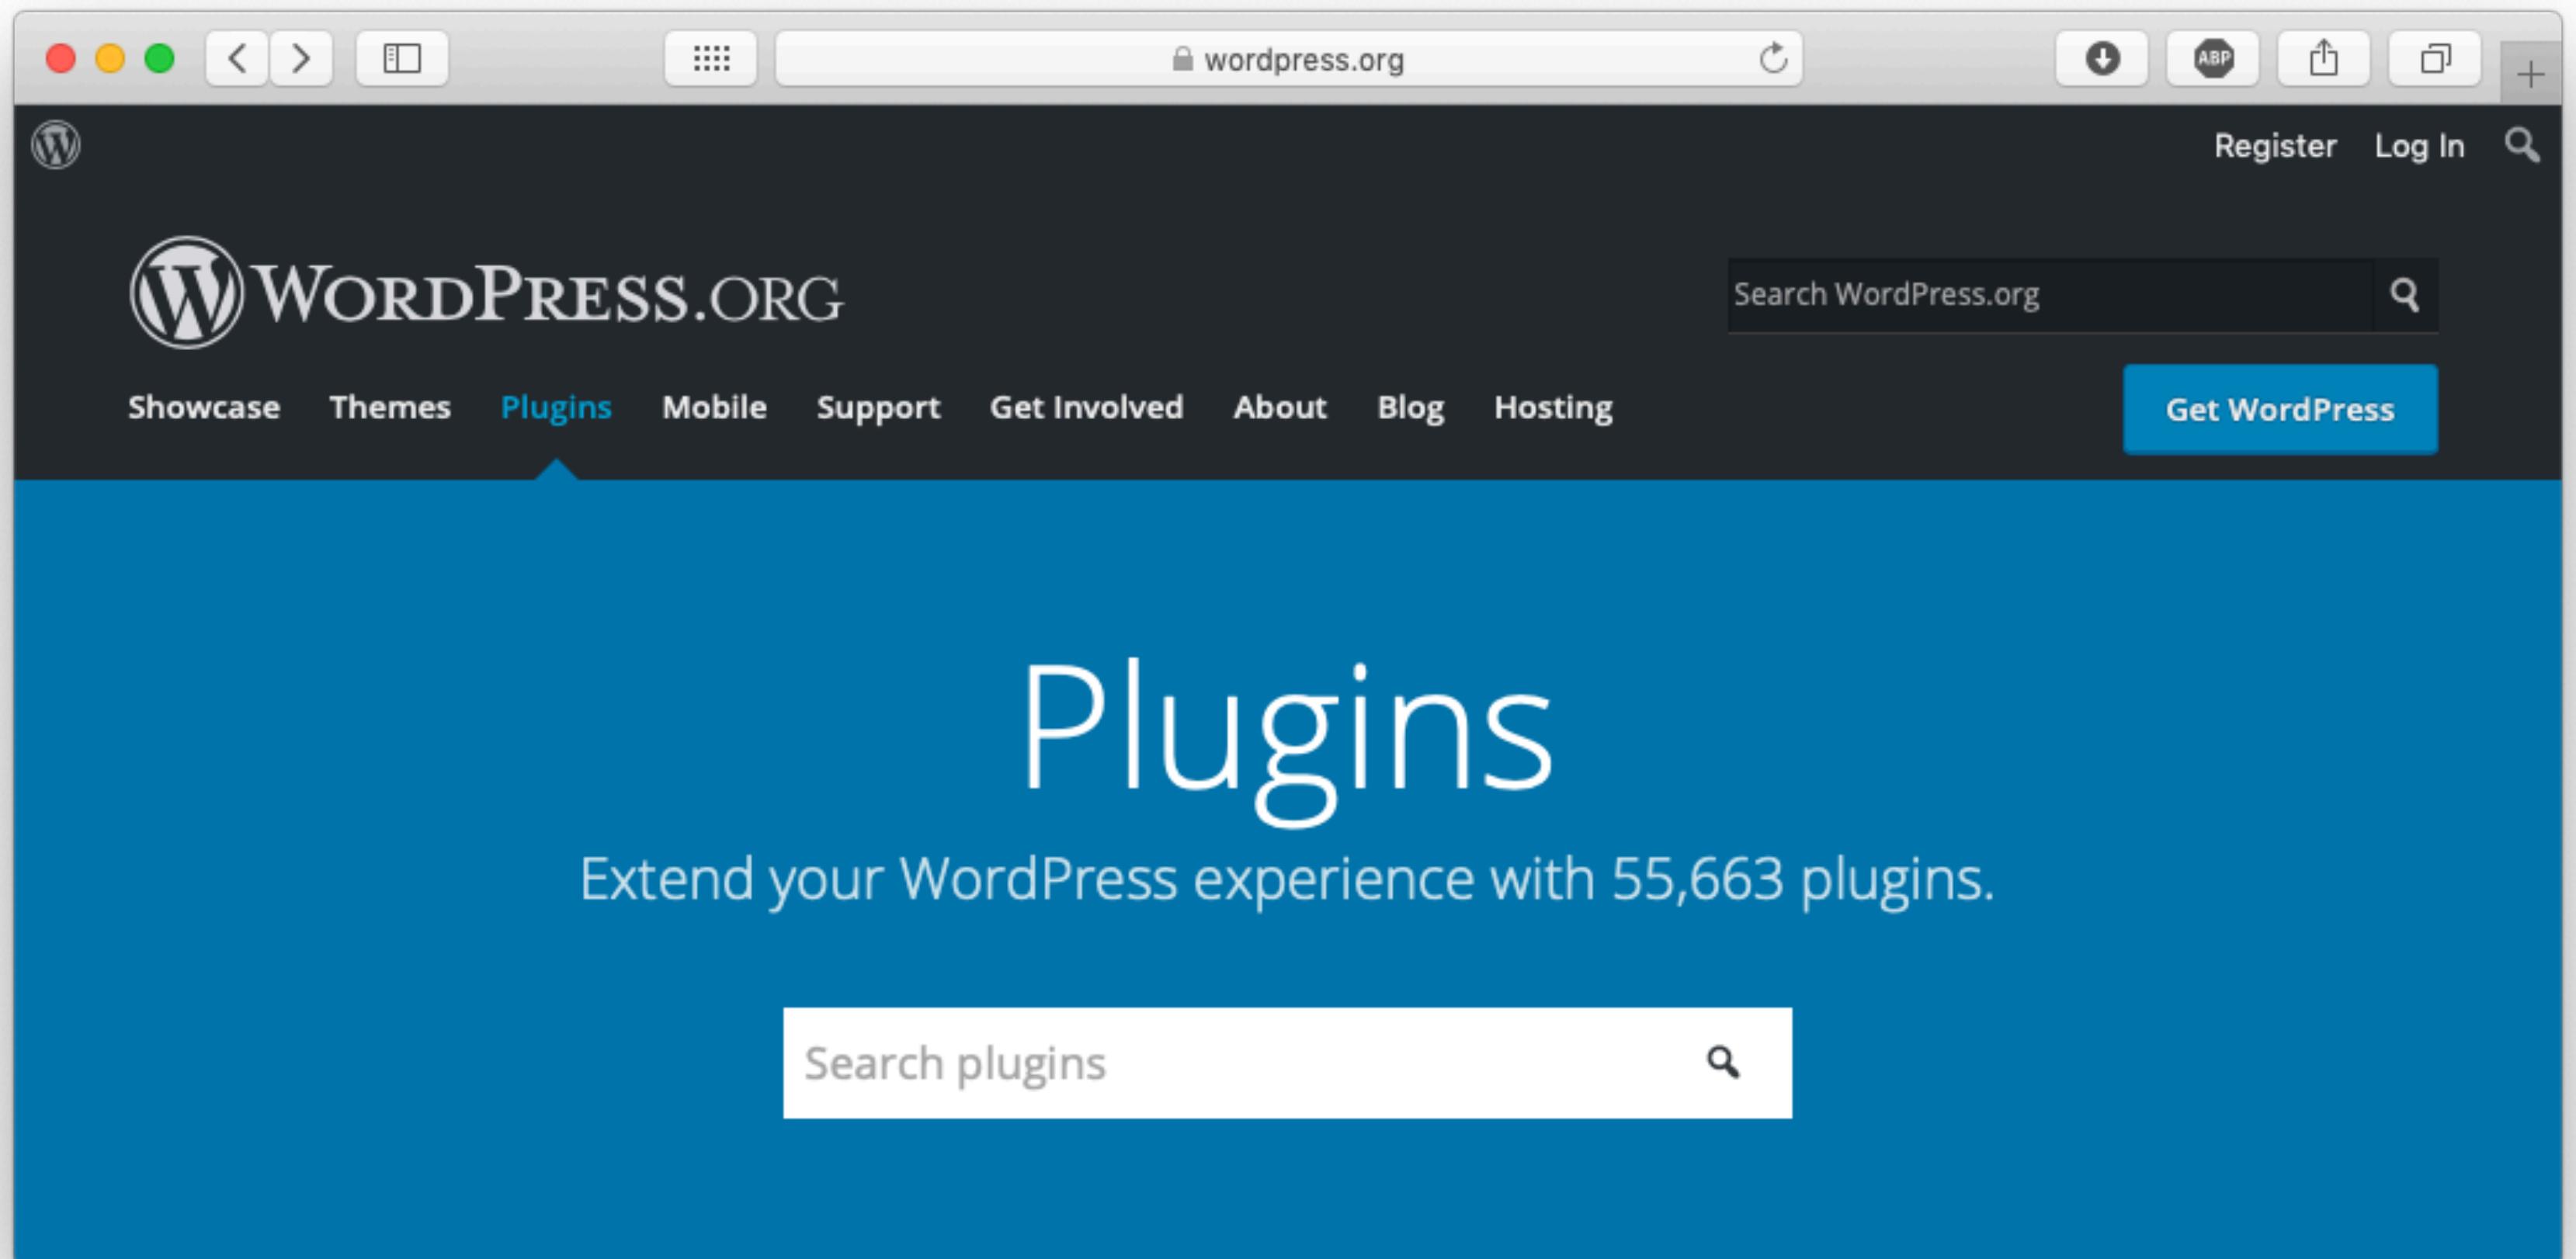

```
OVERVIEW: clang LLVM compiler

USAGE: clang [options] <inputs>

OPTIONS:
-###          Print (but do not run) the commands to run for this compilation
--analyzer-output <value>
               Static analyzer report output format (html|plist|plist-multi|file|plist-html|text).
--analyze      Run the static analyzer
--arcmt-migrate-errors
               Emit ARC errors even if the migrator can fix them
--arcmt-migrate-report-output <value>
               Output path for the plist report
-B <dir>     Add <dir> to search path for binaries and object files used implicitly
-CC           Include comments from within macros in preprocessed output
-cfguard     Emit tables required for Windows Control Flow Guard.
-cl-denorms-are-zero OpenCL only. Allow denormals to be flushed to zero.
-cl-fast-relaxed-math OpenCL only. Sets -cl-finite-math-only and -cl-unsafe-math-optimizations, and defines __FAST_RELAXED_MATH__.
-cl-finite-math-only OpenCL only. Allow floating-point optimizations that assume arguments and results are not NaNs or +Inf.
-cl-fp32-correctly-rounded-divide-sqrt
               OpenCL only. Specify that single precision floating-point divide and sqrt used in the program source are correctly rounded.
-cl-kernel-arg-info OpenCL only. Generate kernel argument metadata.
-cl-mad-enable   OpenCL only. Allow use of less precise MAD computations in the generated binary.
-cl-no-signed-zeros OpenCL only. Allow use of less precise no signed zeros computations in the generated binary.
-cl-opt-disable  OpenCL only. This option disables all optimizations. By default optimizations are enabled.
-cl-single-precision-constant
               OpenCL only. Treat double precision floating-point constant as single precision constant.
-cl-std=<value> OpenCL language standard to compile for.
-cl-strict-aliasing OpenCL only. This option is added for compatibility with OpenCL 1.0.
-cl-uniform-work-group-size
               OpenCL only. Defines that the global work-size be a multiple of the work-group size specified to clEnqueueNDRangeKernel
-cl-unsafe-math-optimizations
               OpenCL only. Allow unsafe floating-point optimizations. Also implies -cl-no-signed-zeros and -cl-mad-enable.
--config <value> Specifies configuration file
--cuda-compile-host-device
               Compile CUDA code for both host and device (default). Has no effect on non-CUDA compilations.
--cuda-device-only Compile CUDA code for device only
--cuda-gpu-arch=<value> CUDA GPU architecture (e.g. sm_35). May be specified more than once.
--cuda-host-only  Compile CUDA code for host only. Has no effect on non-CUDA compilations.
--cuda-include-ptx=<value>
               Include PTX for the following GPU architecture (e.g. sm_35) or 'all'. May be specified more than once.
--cuda-noot-device-debug
               Enable device-side debug info generation. Disables ptxas optimizations.
--cuda-path-ignore-env Ignore environment variables to detect CUDA installation
--cuda-path=<value> CUDA installation path
-cxx-isystem <directory>
               Add directory to the C++ SYSTEM include search path
-C             Include comments in preprocessed output
-c             Only run preprocess, compile, and assemble steps
-dD            Print macro definitions in -E mode in addition to normal output
-dependency-dot <value> Filename to write DOT-formatted header dependencies to
-dependency-file <value>
               Filename (or -) to write dependency output to
-dI            Print include directives in -E mode in addition to normal output
-dM            Print macro definitions in -E mode instead of normal output
-D <macro>=<value> Define <macro> to <value> (or 1 if <value> omitted)
-emit-ast     Emit Clang AST files for source inputs
-emit-llvm    Use the LLVM representation for assembler and object files
-enable-trivial-auto-var-init-zero-knowing-it-will-be-removed-from-clang<value>
               Trivial automatic variable initialization to zero is only here for benchmarks, it'll eventually be removed, and I'm OK with that because I'm only using it to
benchmark
-E             Only run the preprocessor
-faddrsig     Emit an address-significance table
-faligned-allocation Enable C++17 aligned allocation functions
-fallow-editor-placeholders
               Treat editor placeholders as valid source code
-fansi-escape-codes Use ANSI escape codes for diagnostics
-fapinotes-cache-path=<directory>
               Does nothing; API notes are no longer cached separately from modules
-fapinotes-modules Enable module-based external API notes support

software variability is the ability of a software system or artefact to be efficiently extended, changed, **customised** or configured for use in a **particular context**.

Does your application have variability?

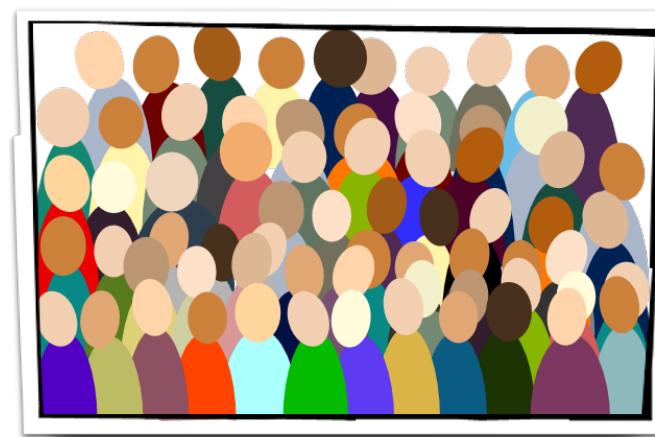

Yes, most probably

Example: SAP, an Enterprise Resource Planning system (ERP)

Integrated management of business processes and operational data

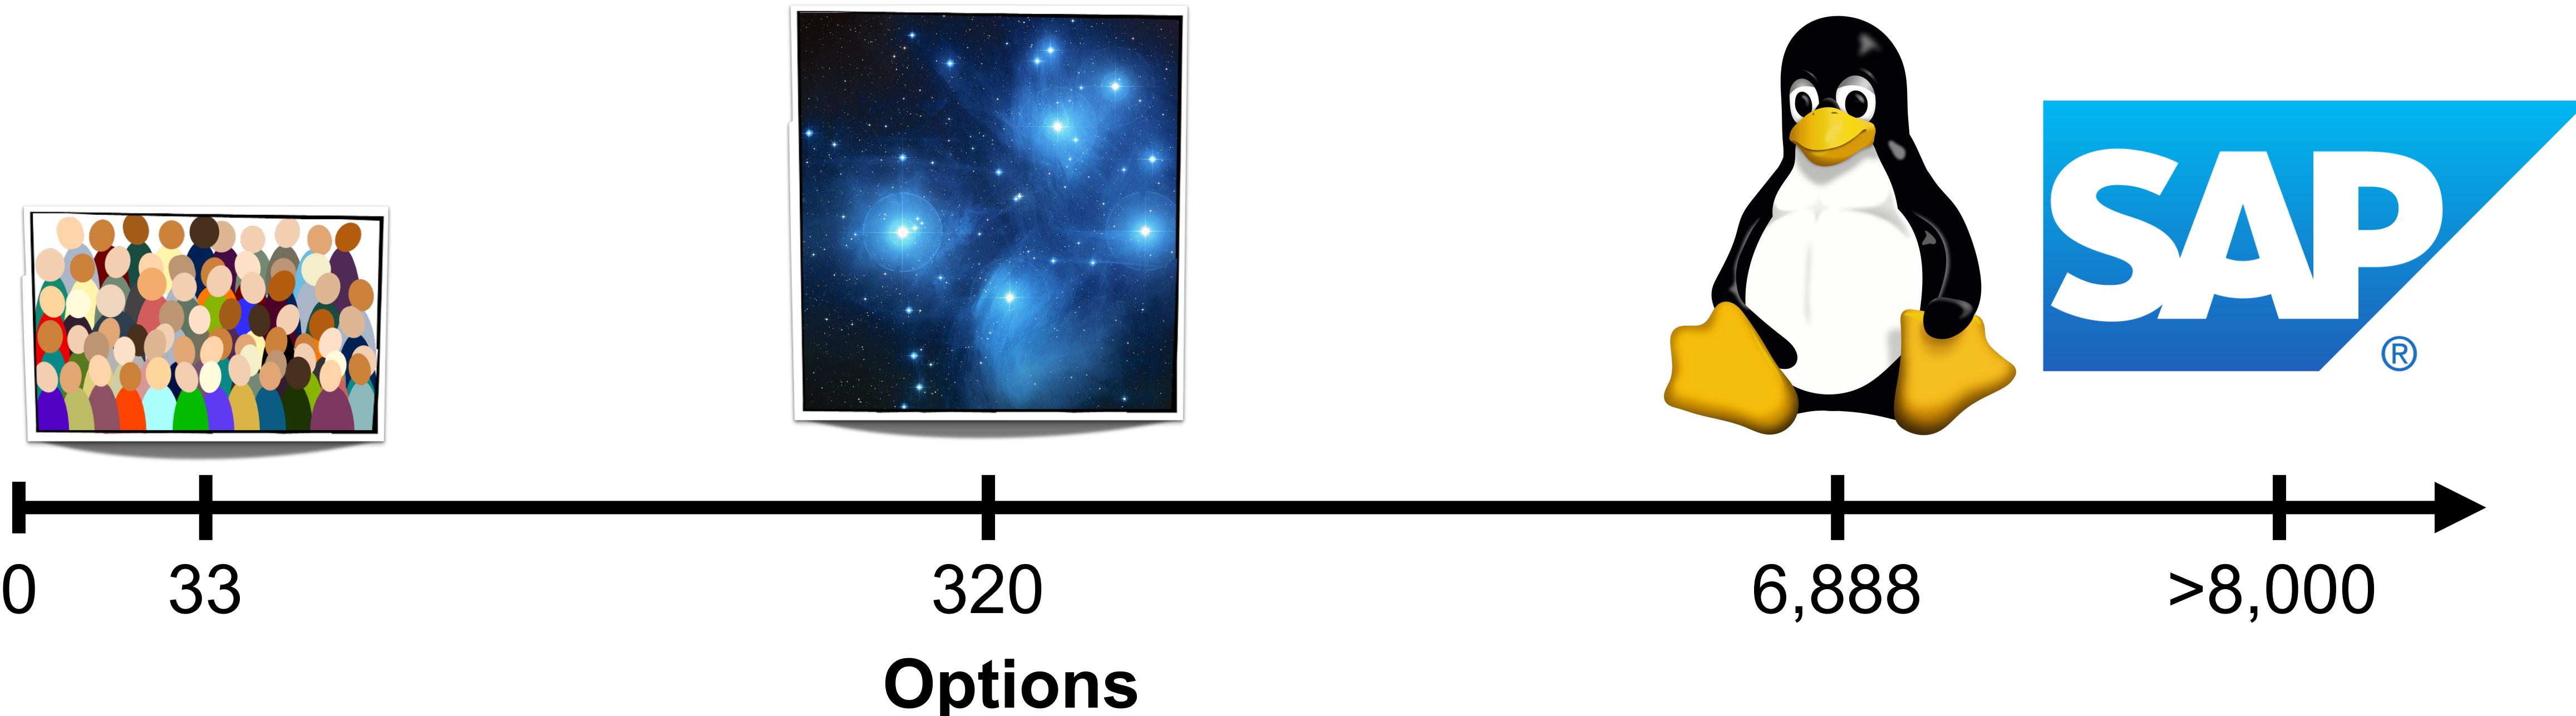

ERPs in numbers

- SAP was founded in 1972
 - Designed to be extensible from the beginning
- Every year (worldwide)...
 - companies spend \$41B on ERPs
 - SAP alone sells for \$25B
 - SAP systems manage 77% of the world's transaction revenue, and 78% of the world's food

A basic SAP installation has 20,000 database tables,
3,000 are configuration tables

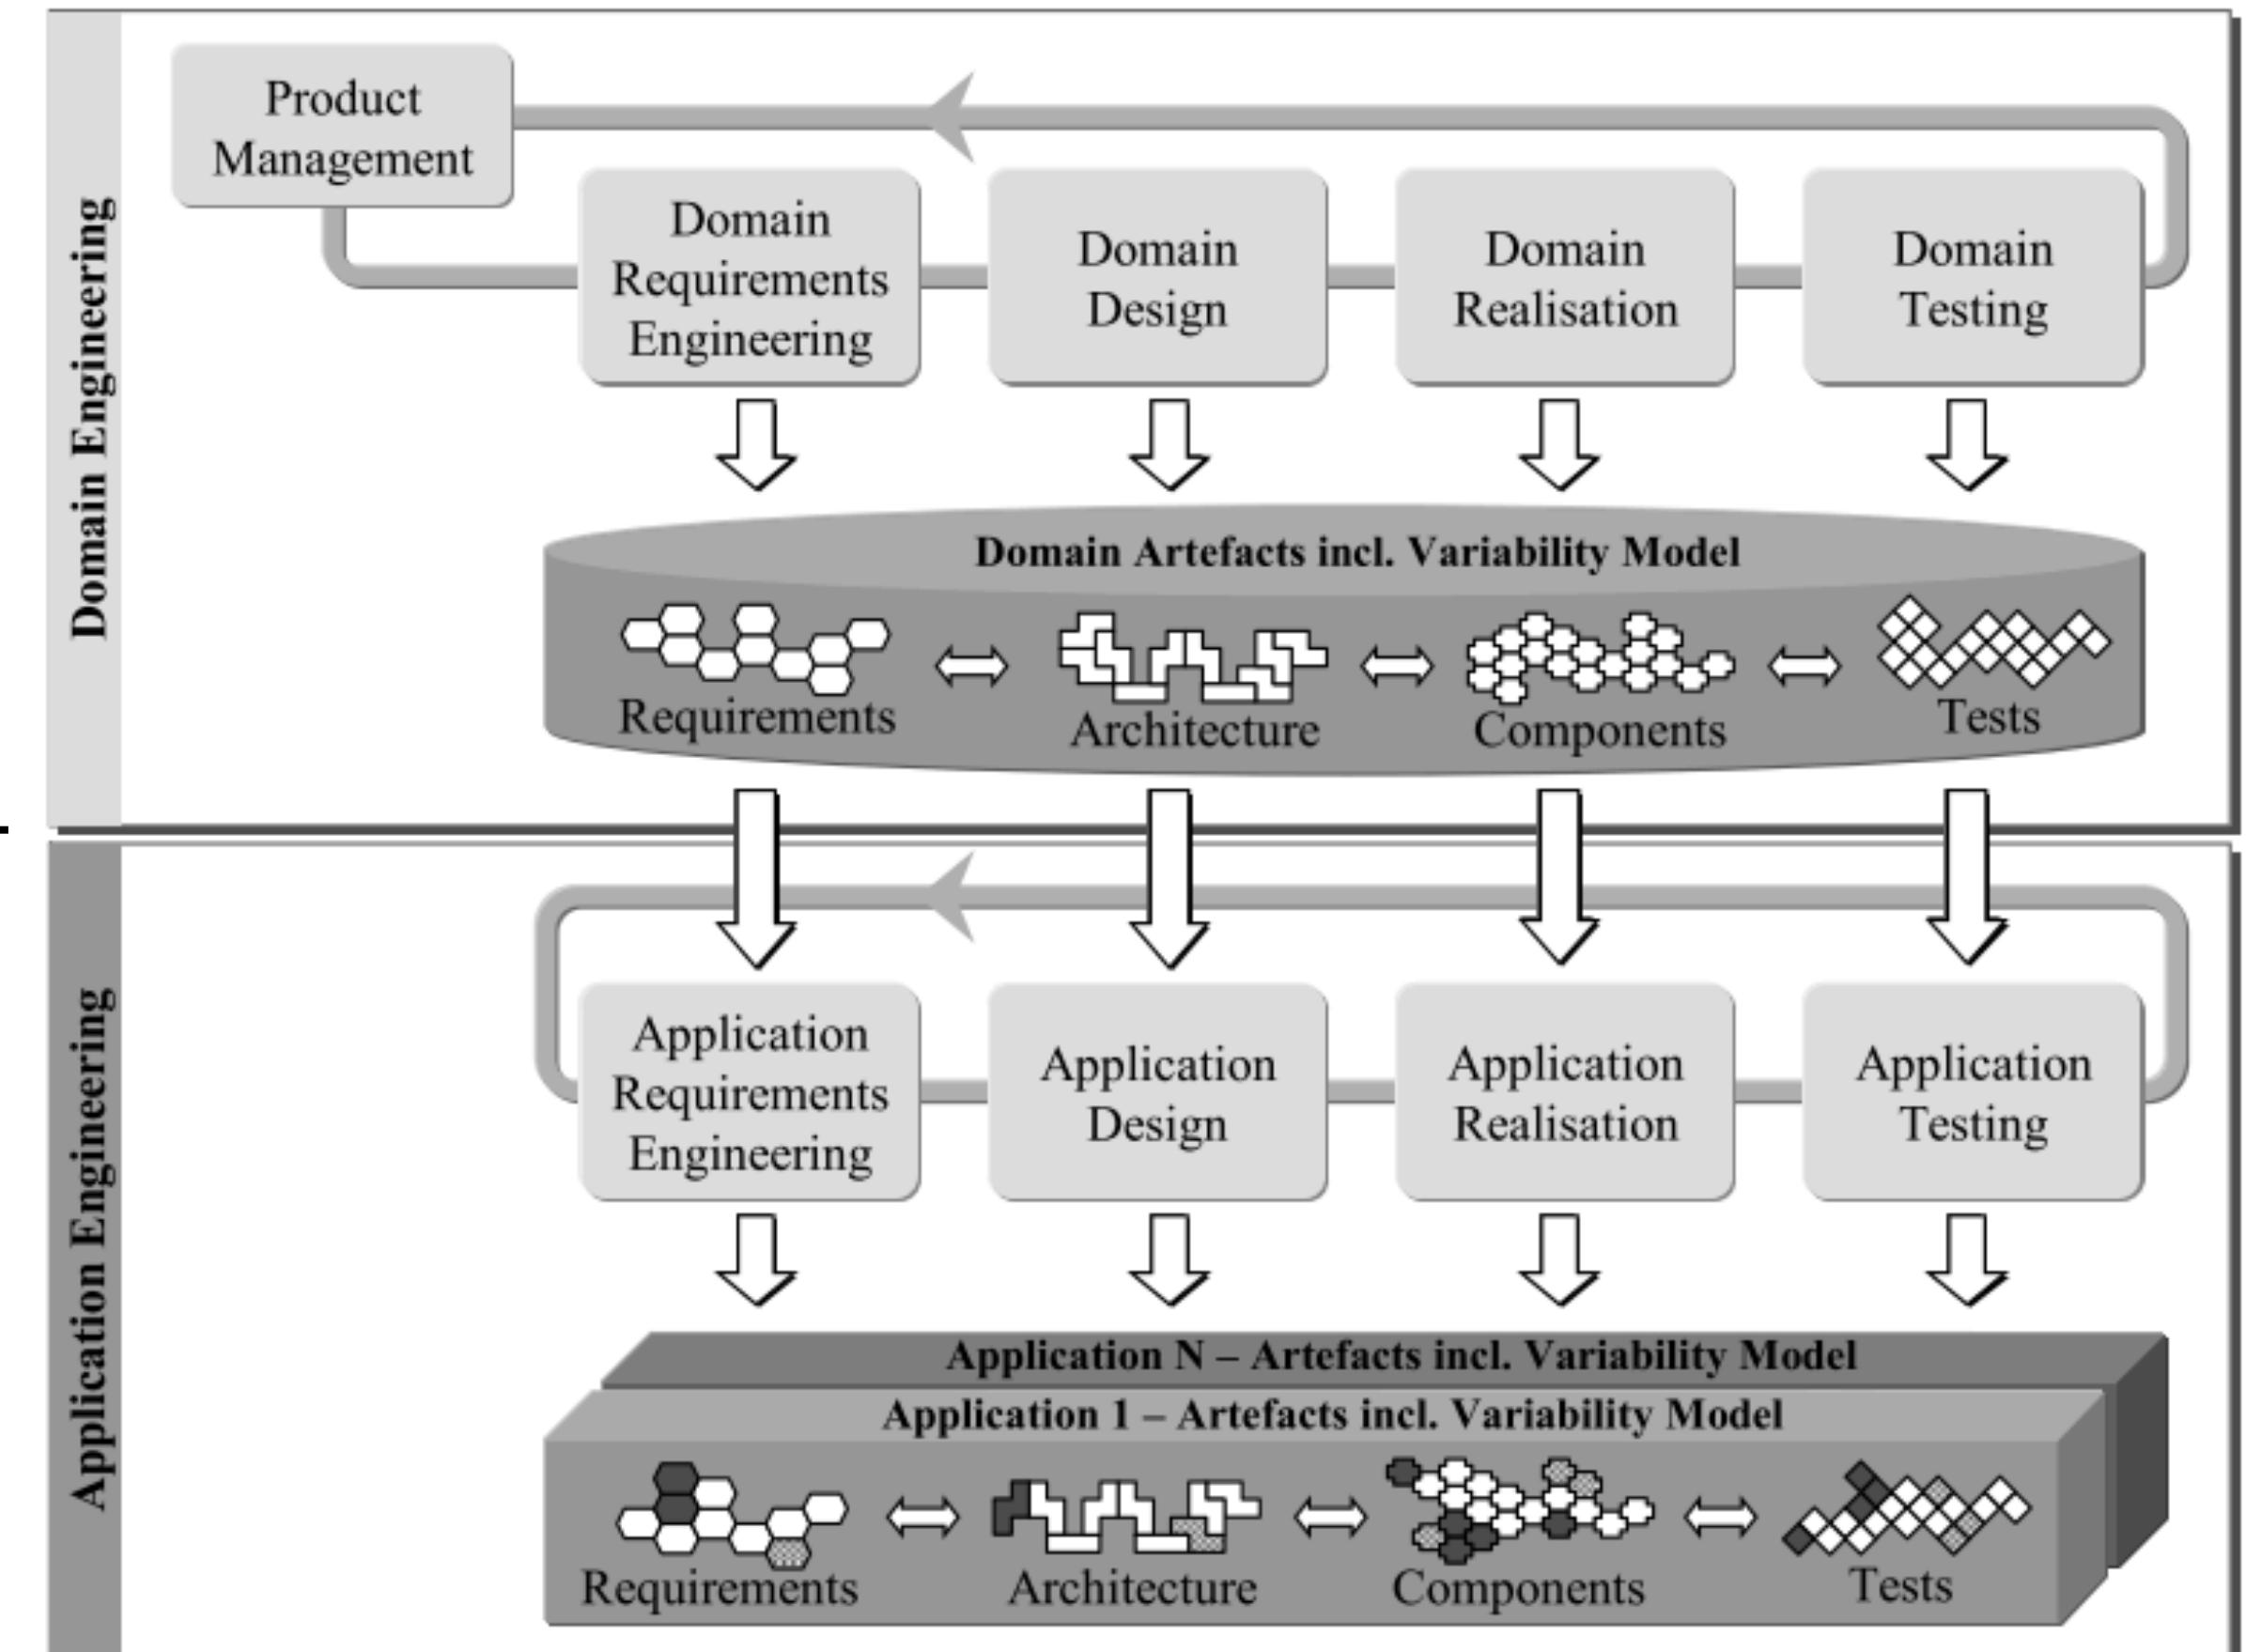

SAP requires ~8,000 configuration decisions at setup
☞ *SAP Configuration Specialist* is an actual job title!

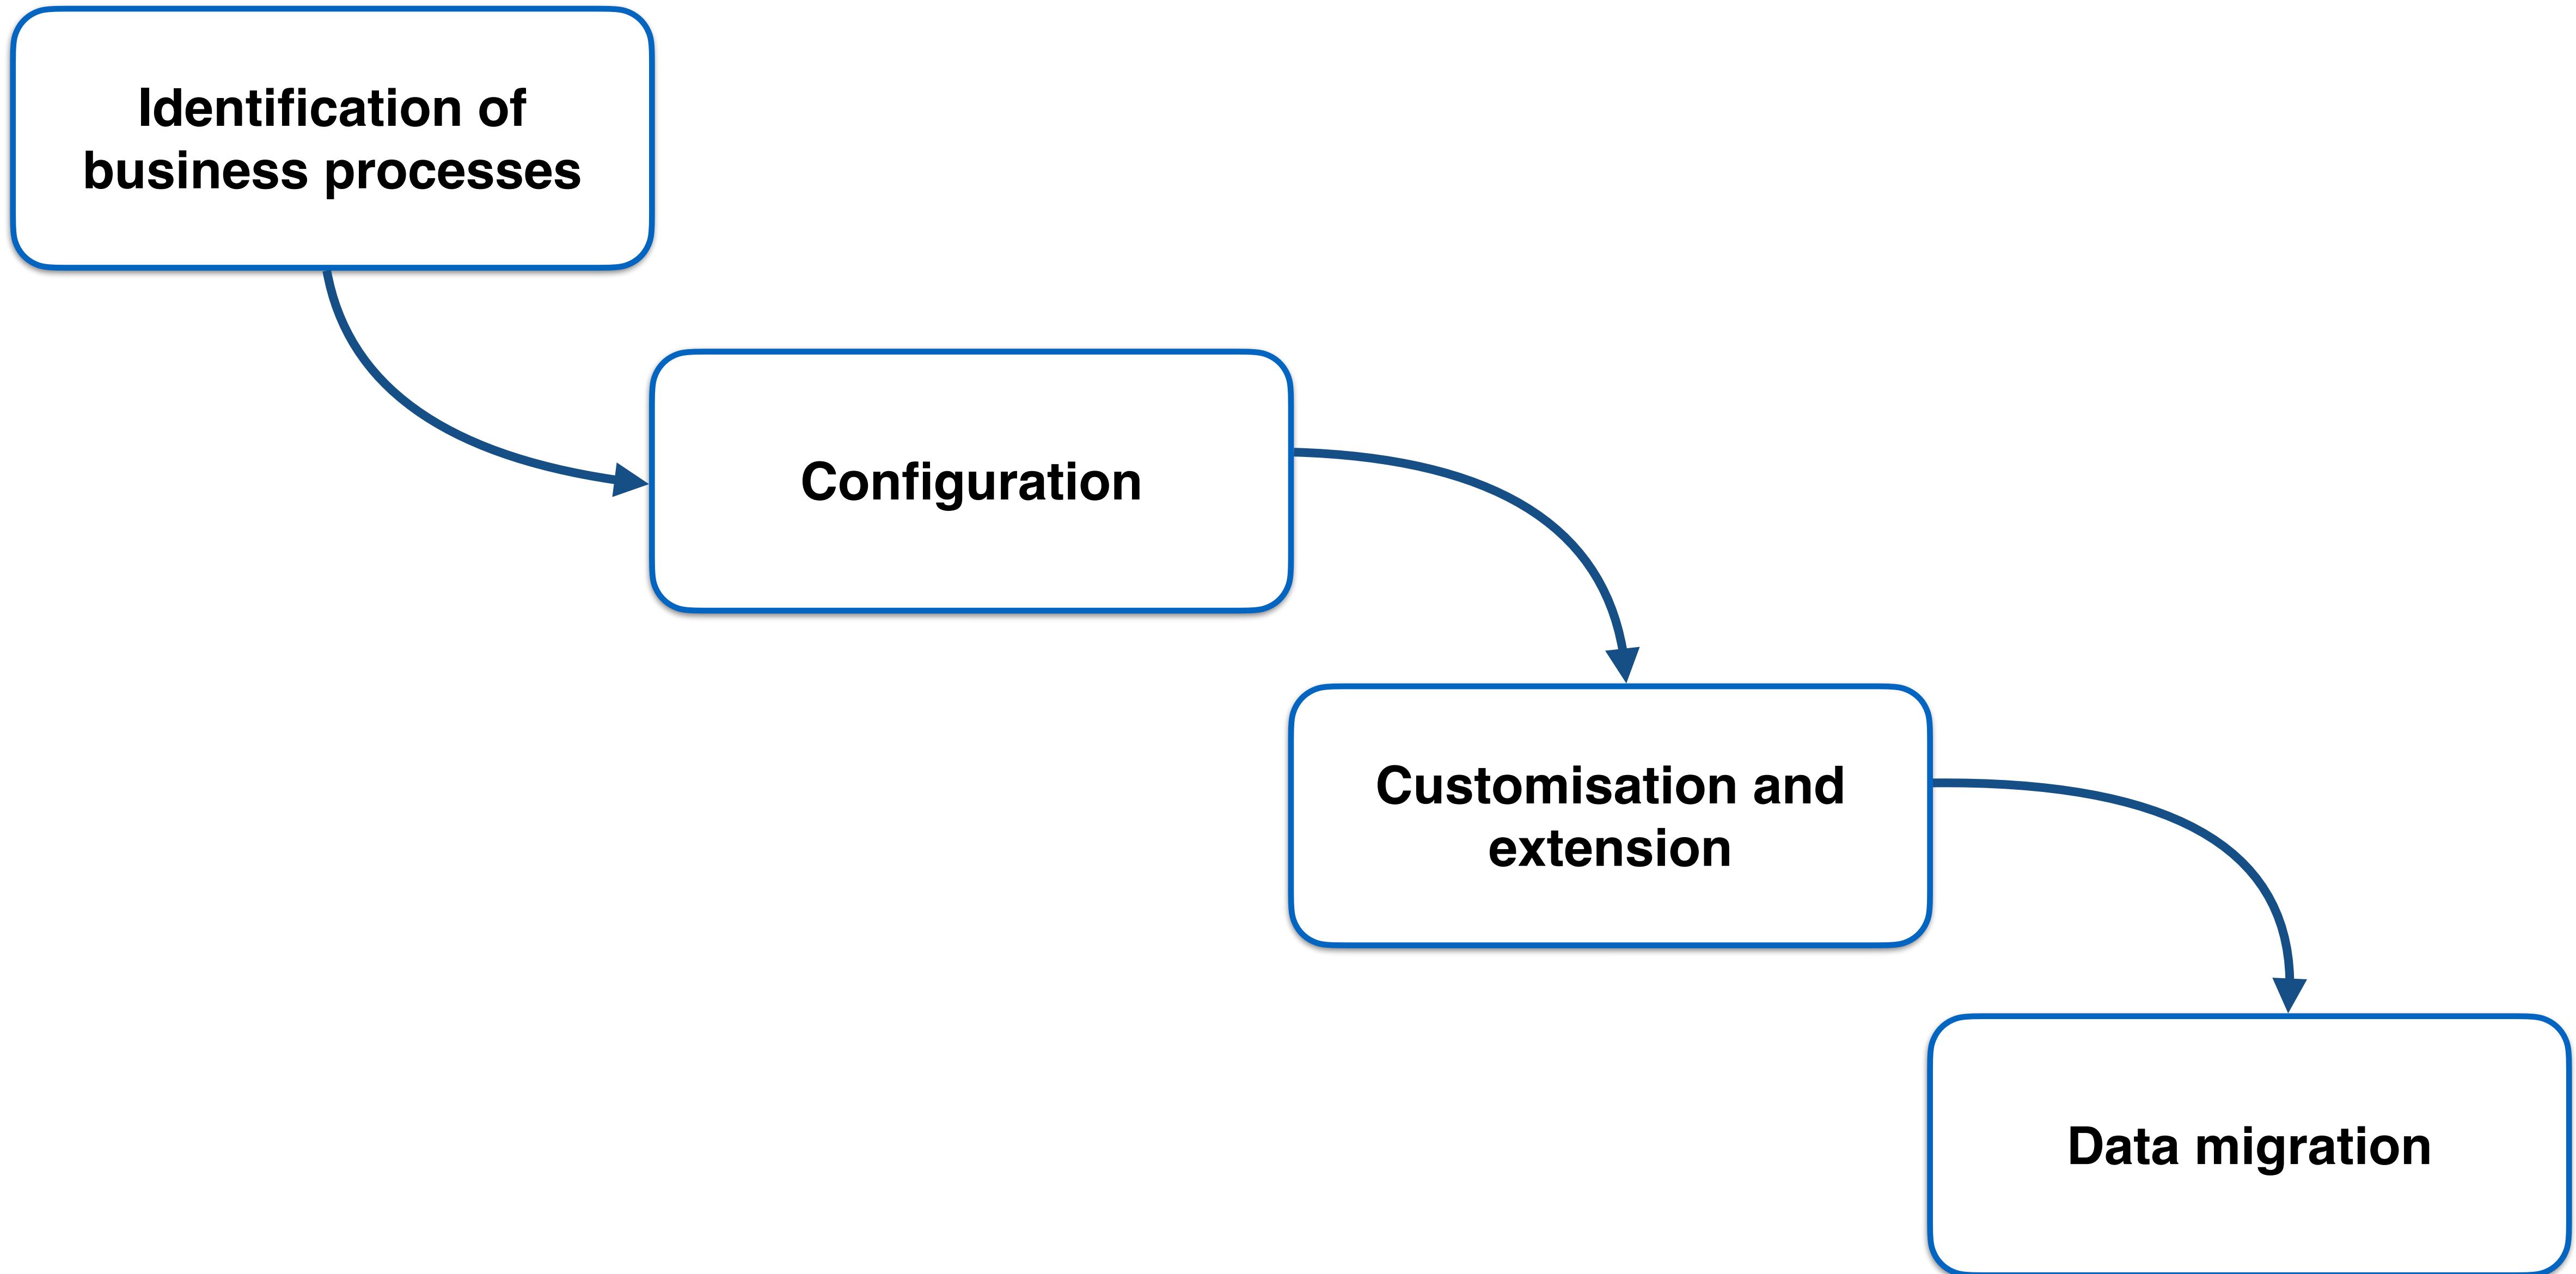

ERPs in numbers

- Switching to an ERP
 - Costs \$100 million to \$500 million
 - \$30 million in software license fees,
 - \$200 million in consulting fees,
 - millions for hardware,
 - and millions to train managers and employees.
 - Takes from four to six years
- Examples
 - Cisco's ERP implementation took 9 months and \$15 million (best case)
 - Dow Chemical's implementation took 8 years and \$1 billion
 - the U.S. navy spent \$1 billion on four different ERP projects that all failed

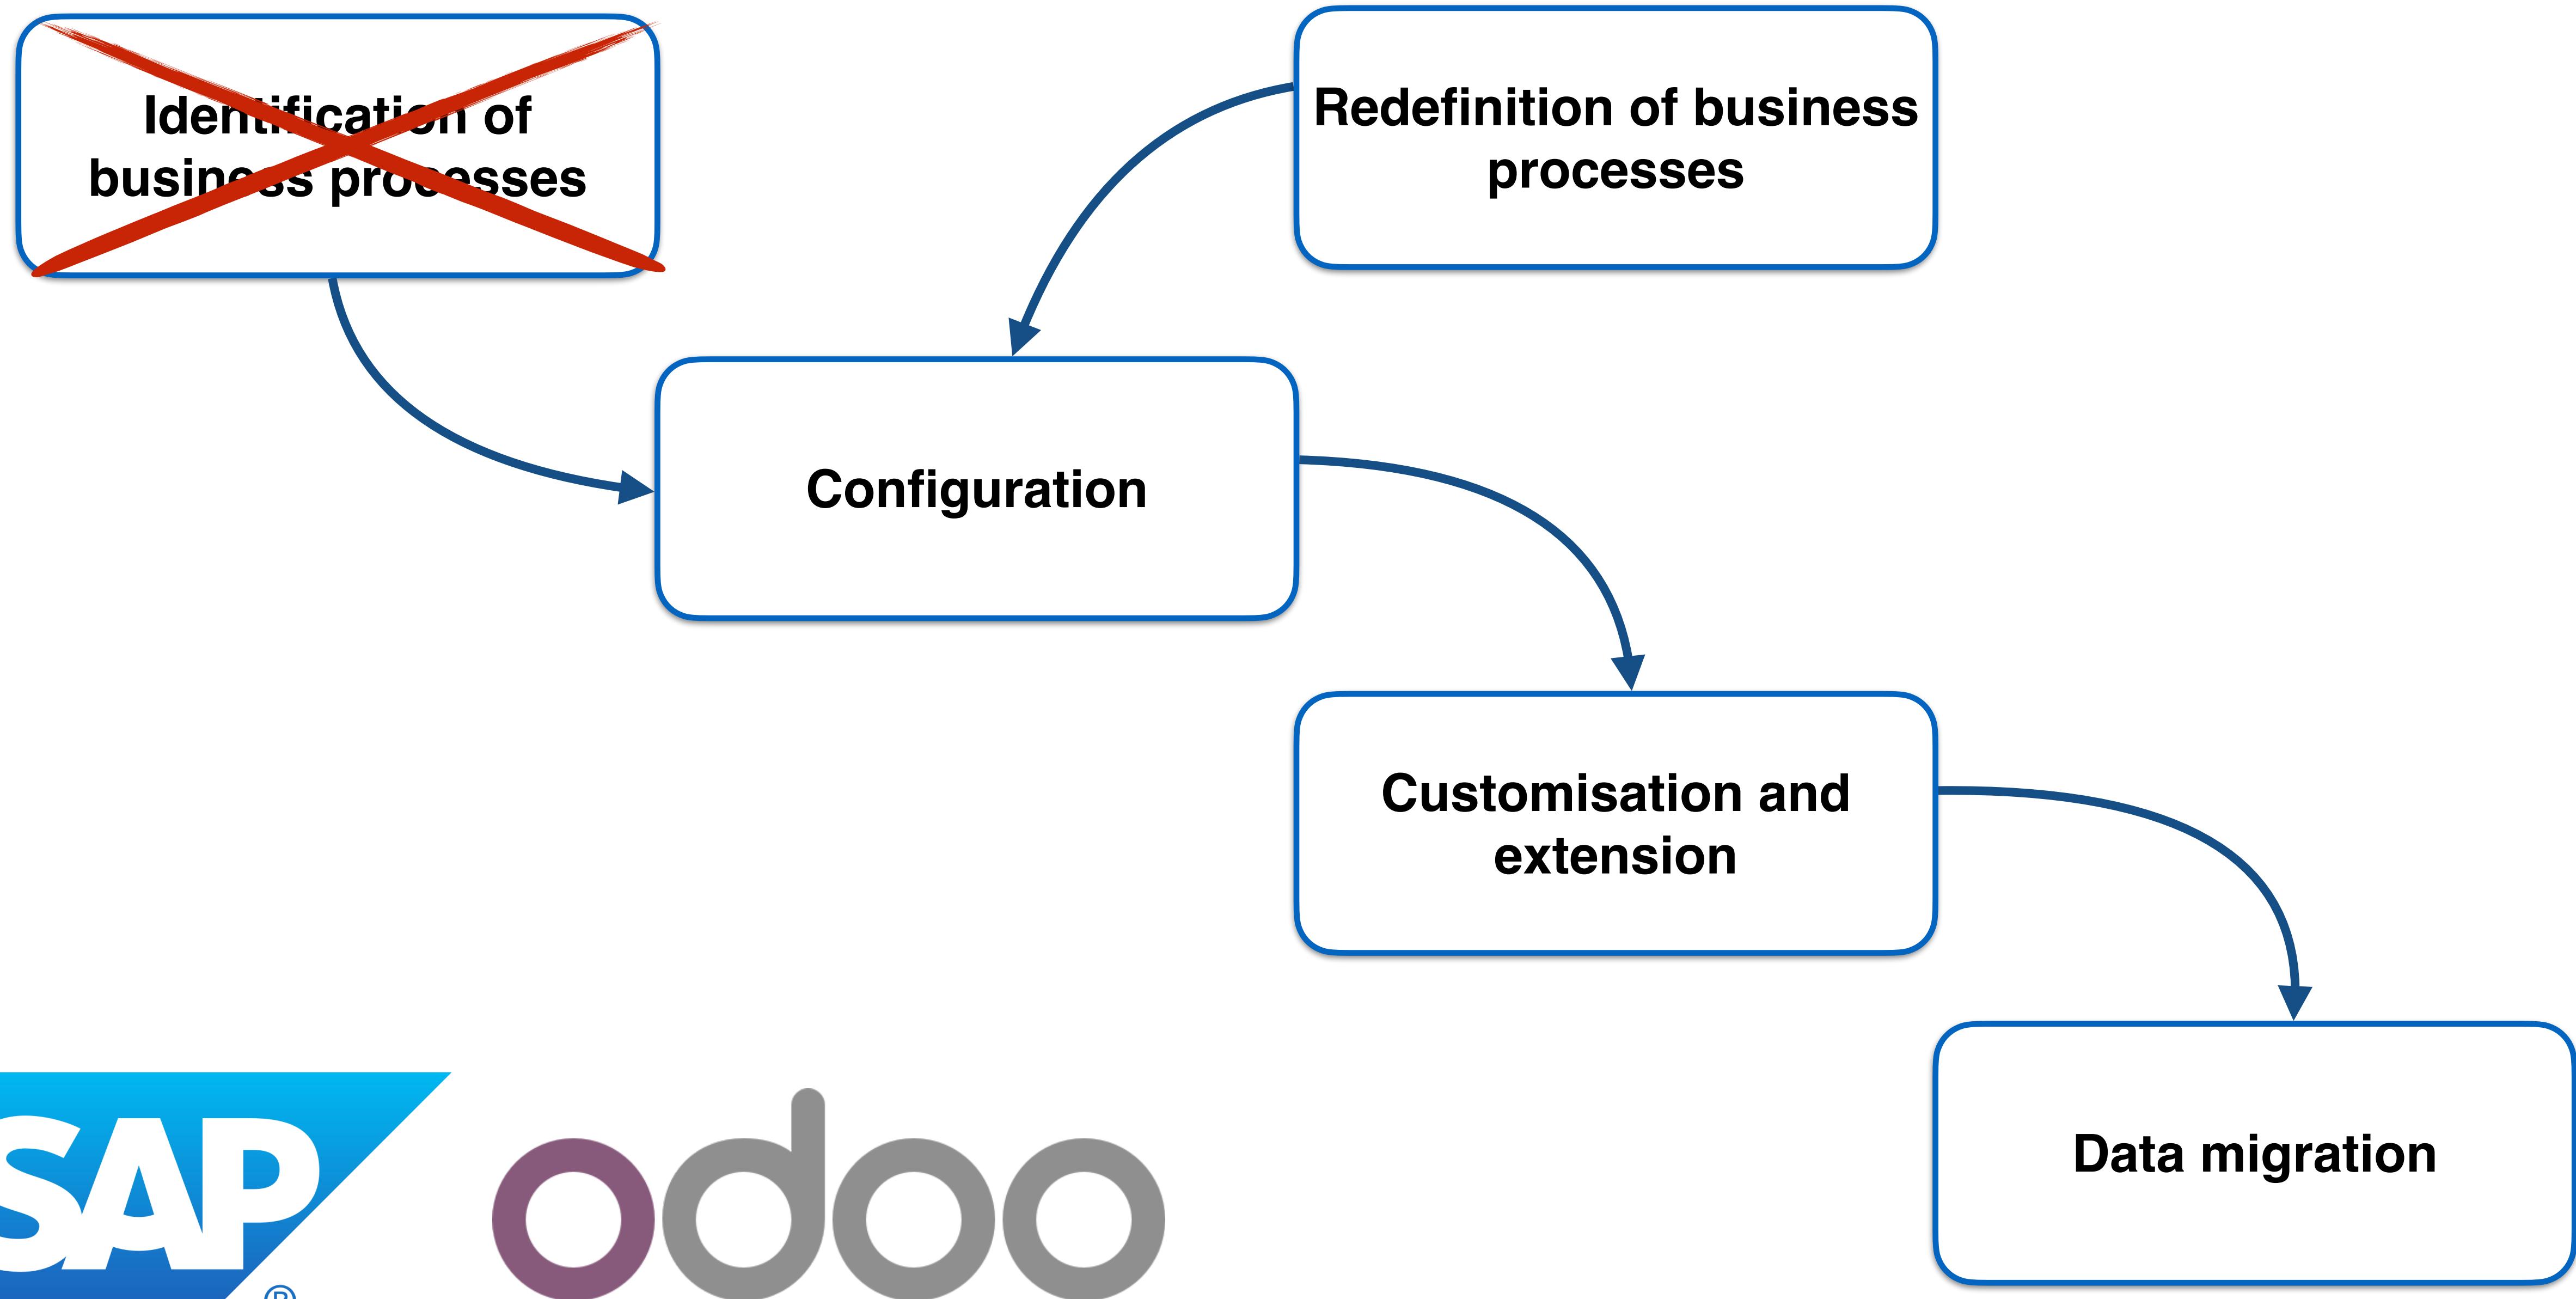

- Building the ERP platform
 - Core
 - API
 - Modules
 - Configuration workflow

- **Tailor-made**
 - For individual customers
- **Reduced costs**
 - Reusable parts can be combined in different ways
- **Improved quality**
 - Parts can be standardized and checked in isolation and reused and tested in multiple products.
- **Time to market**
 - building on top of existing parts is much faster than developing it entirely from scratch

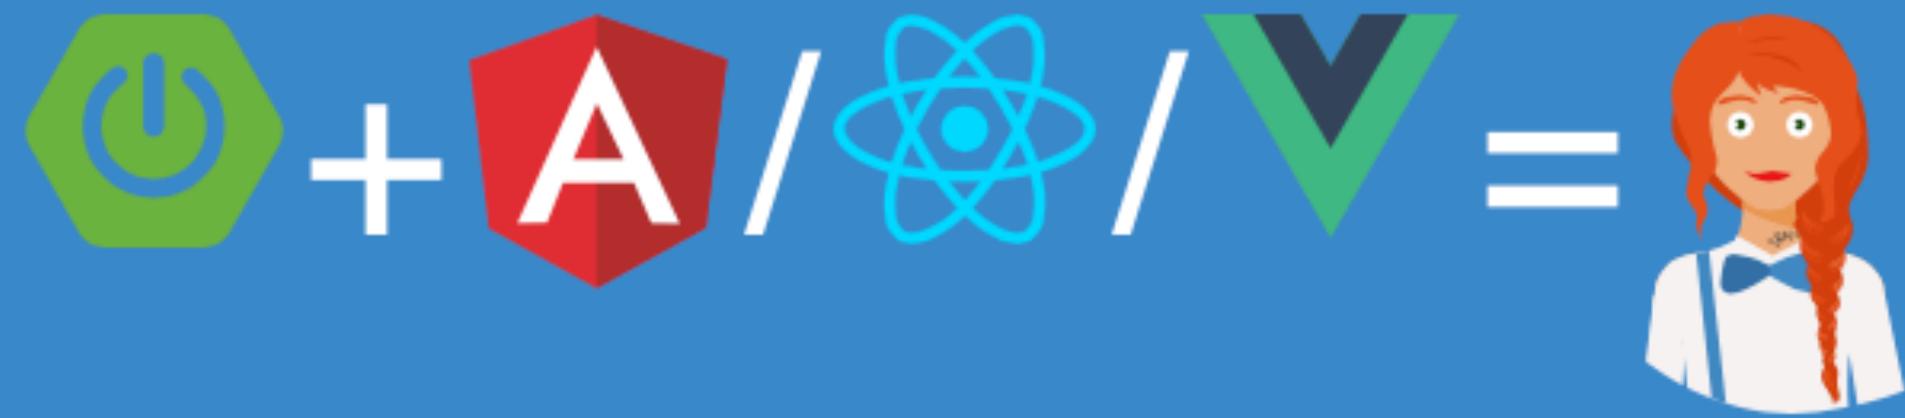

Greetings, Java Hipster!

Feature Modelling

What Is JHipster?

JHipster is a development platform to quickly generate, develop, and deploy modern web applications and microservice architectures. We support many frontend technologies, including Angular, React, and Vue. We even have mobile app support for Ionic and React Native! On the backend, we support Spring Boot (with Java or Kotlin), Micronaut, Quarkus, Node.js, and .NET. For deployment, we embrace cloud native principles with Docker and Kubernetes. Deployment support exists for AWS, Azure, Cloud Foundry, Google Cloud Platform, Heroku, and OpenShift.

**A feature model documents
the features of a product line
and their relationships.**

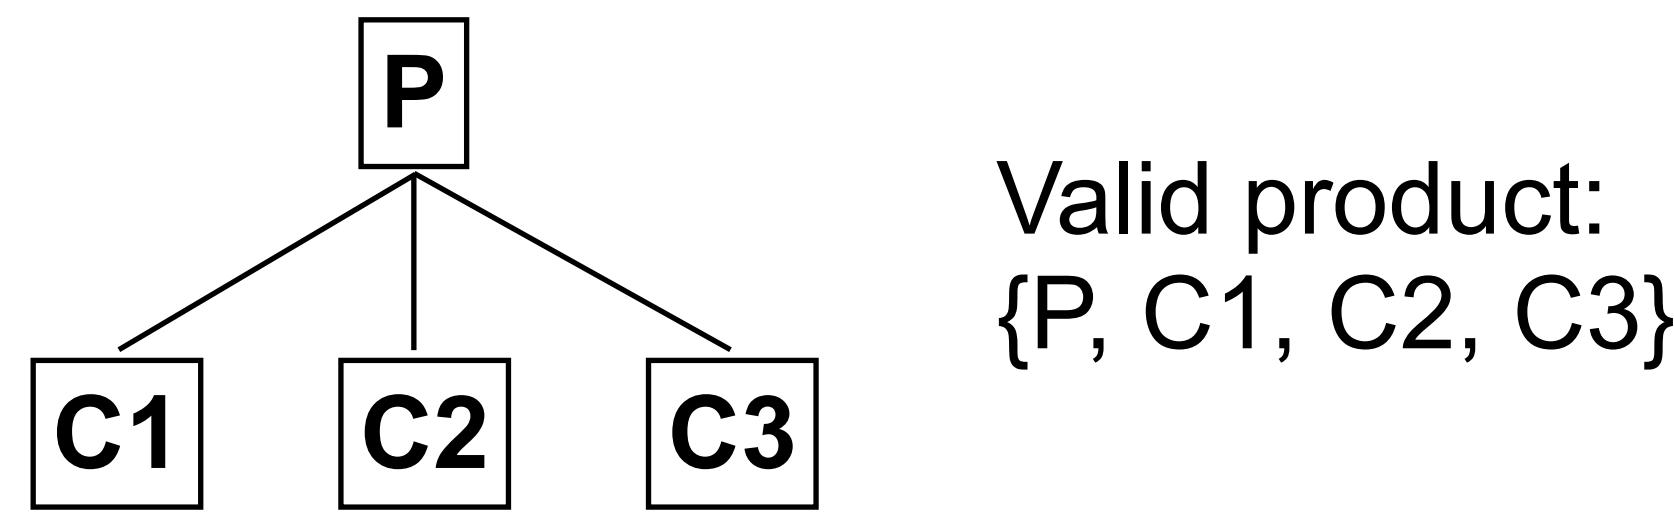

Vocabulary

Feature = Option

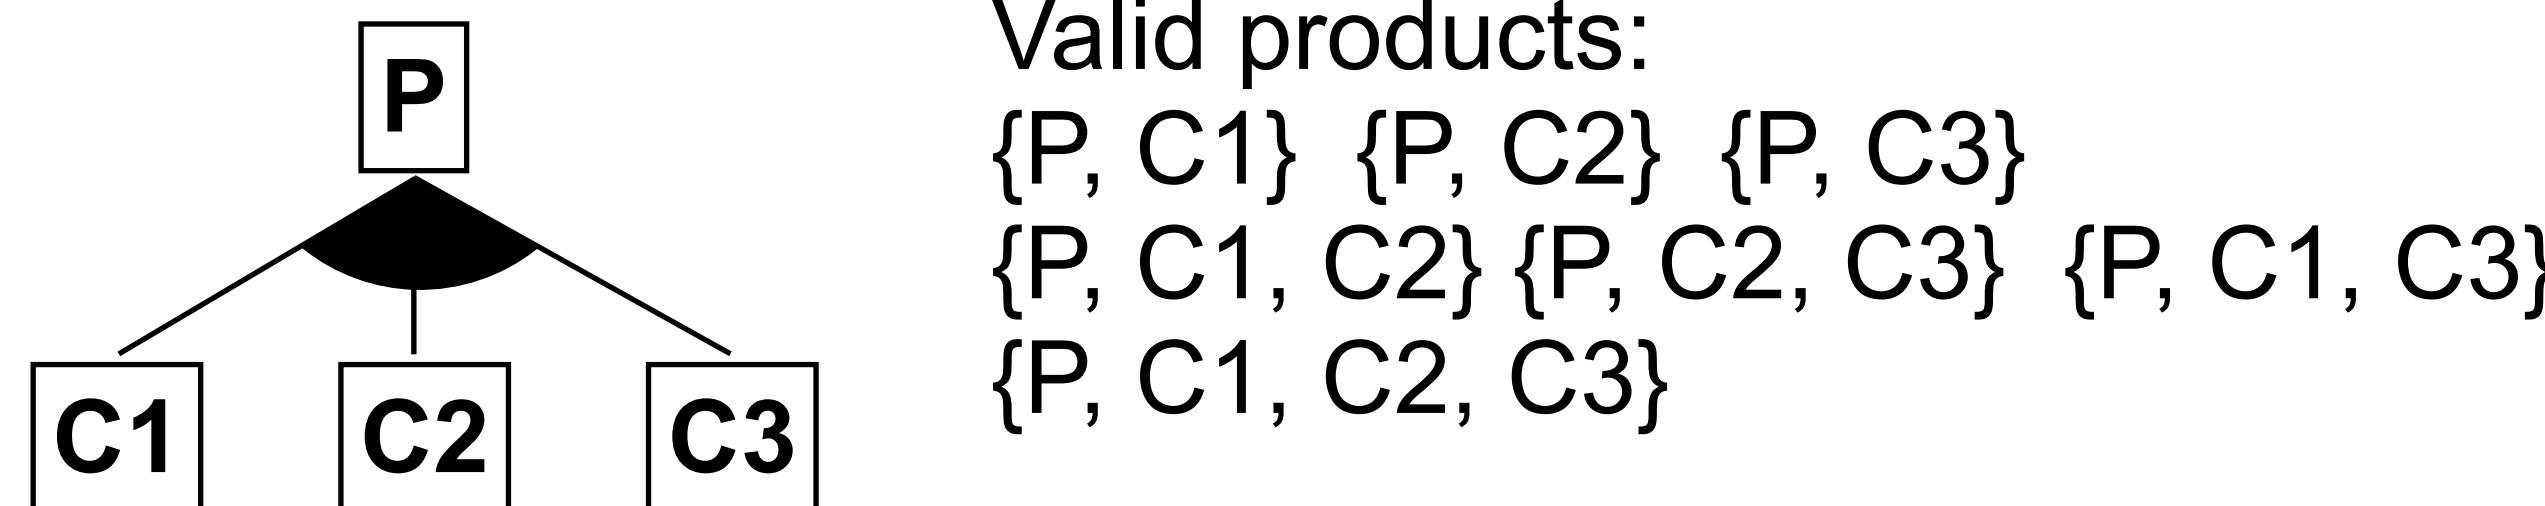

Product = Configuration = Variant

Feature diagram

- **Tree-like** structure (directed acyclic graph).
- A feature is **decomposed** in sub-features
 - **And** decomposition: if the parent is selected then all sub-features must be selected too

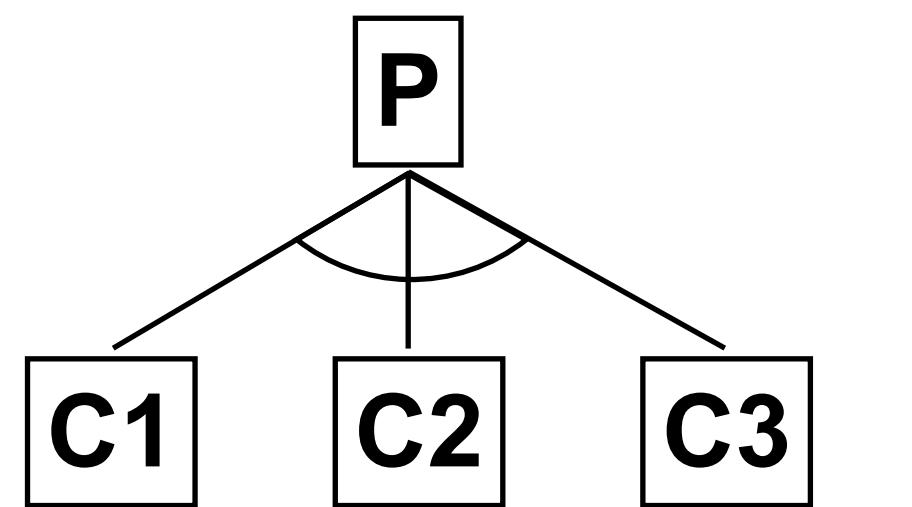

- **Or** decomposition: if the parent is selected then at least one sub-features must be selected too

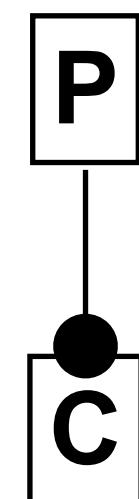

Feature diagram

- **Tree-like** structure (directed acyclic graph).
- A feature is **decomposed** in sub- features
 - **Xor** decomposition: if the parent is selected then exactly one sub-features must be selected too

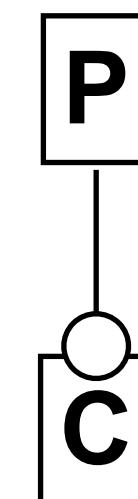

Valid products:
{P, C1}
{P, C2}
{P, C3}

- **Mandatory** feature: if the parent is selected then the feature must be selected

Valid product:
{P, C}

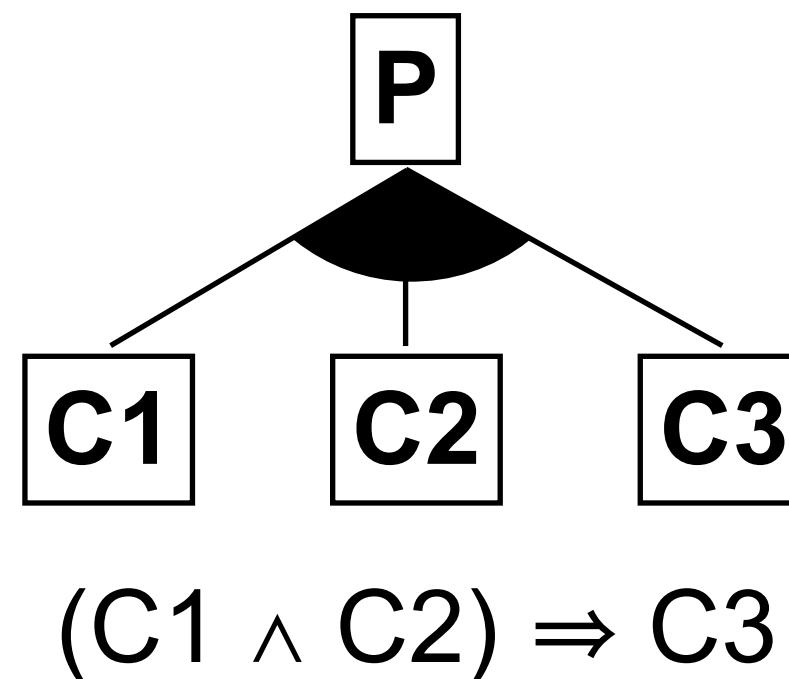

- **Optional** feature: if the parent is selected then the feature must be selected

Valid products:
{P}
{P, C}

Feature diagram

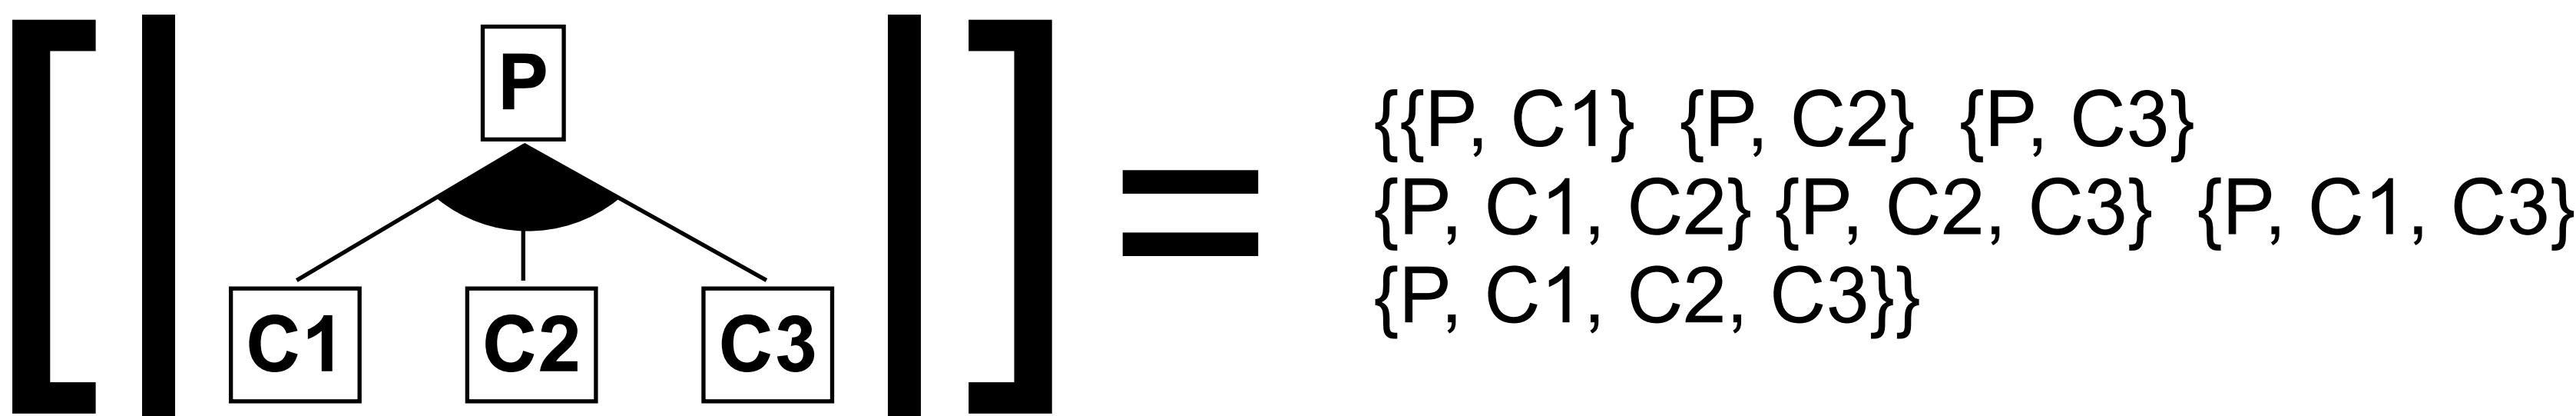

- Cross-tree **constraints** are expressed as boolean expressions over the features.

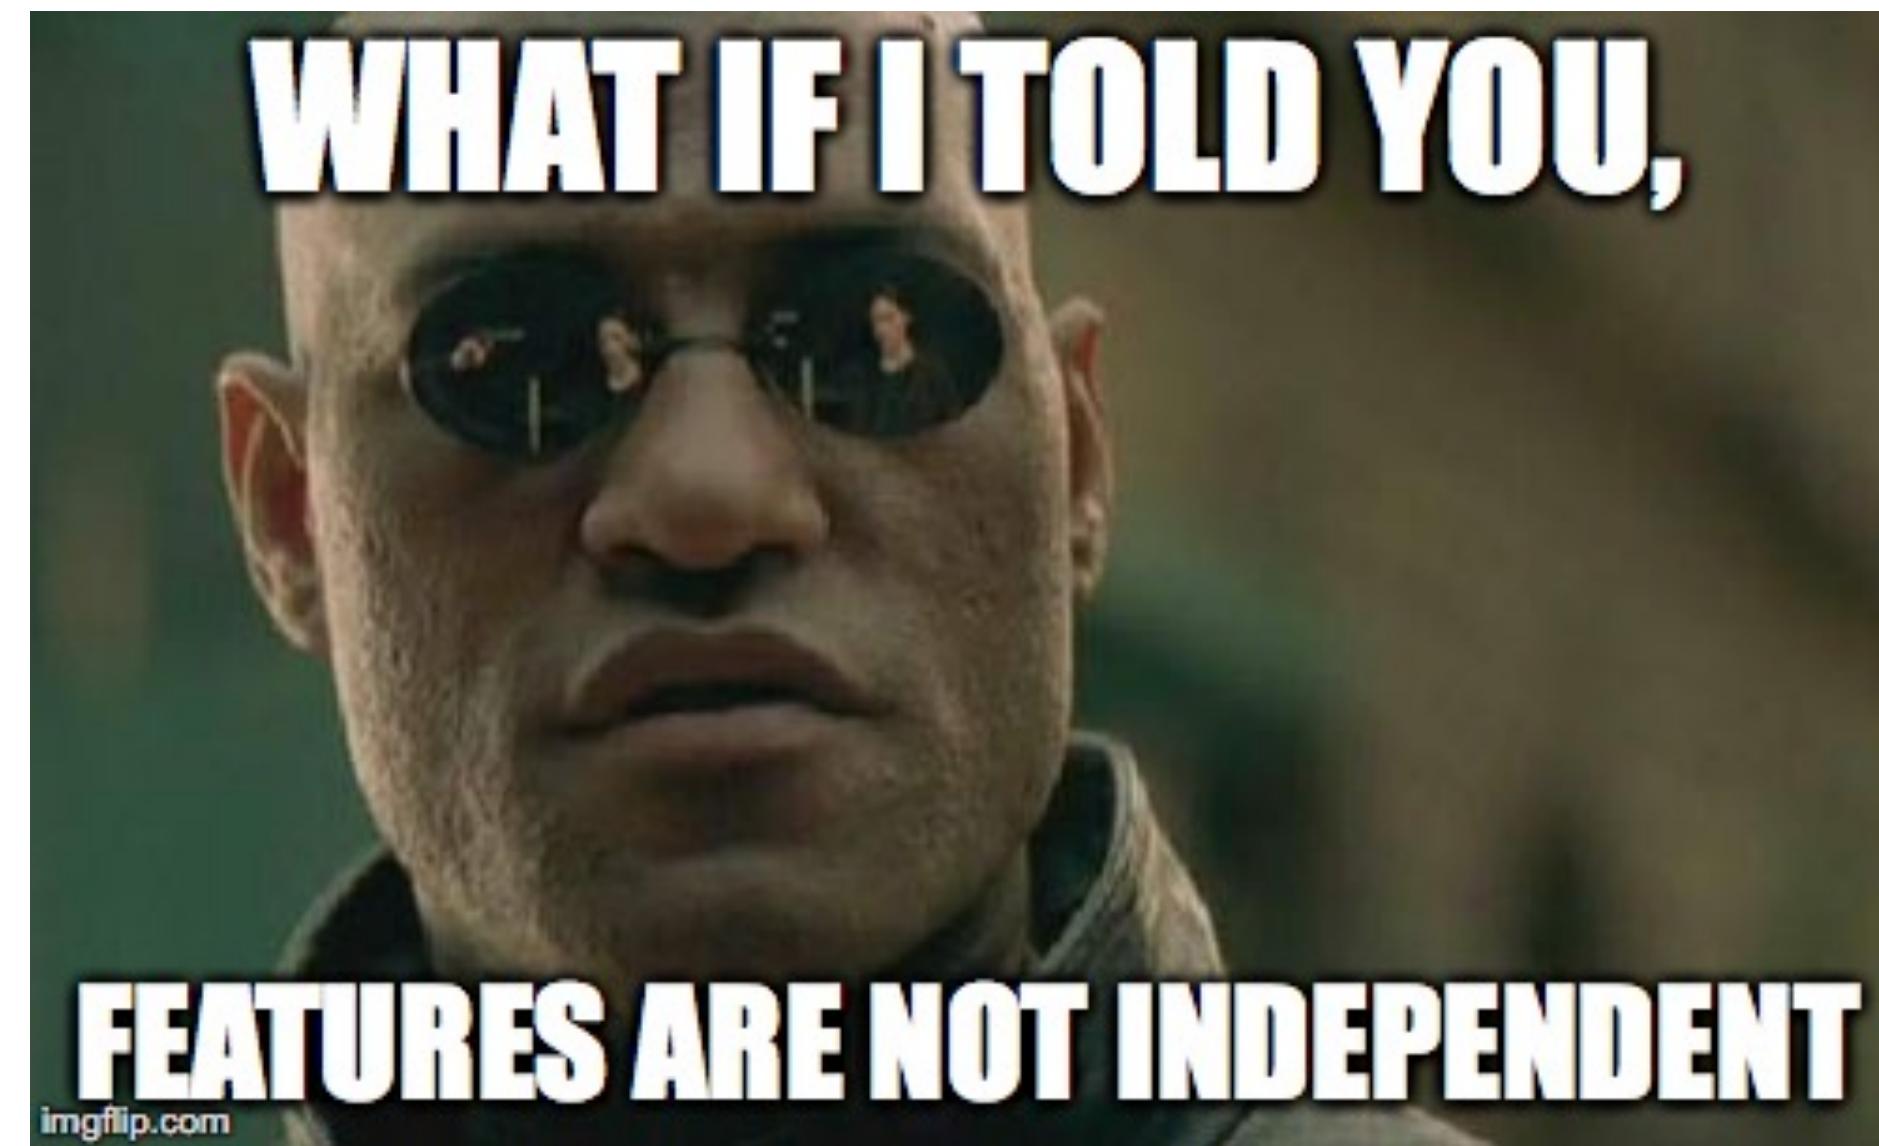

Valid products:

$\{P, C1\}$ $\{P, C2\}$ $\{P, C3\}$
 $\{\cancel{P, C1, C2}\}$ $\{P, C2, C3\}$ $\{P, C1, C3\}$
 $\{P, C1, C2, C3\}$

- The **semantics** of a feature model corresponds to all the **valid products** allowed by the feature model.

Application type

Client side options

Server side options

Which type of application would you like to create?

- Monolithic application (recommended for simple projects)
- Microservice application
- Microservice gateway
- JHipster UAA server (for microservice OAuth2 authentication)

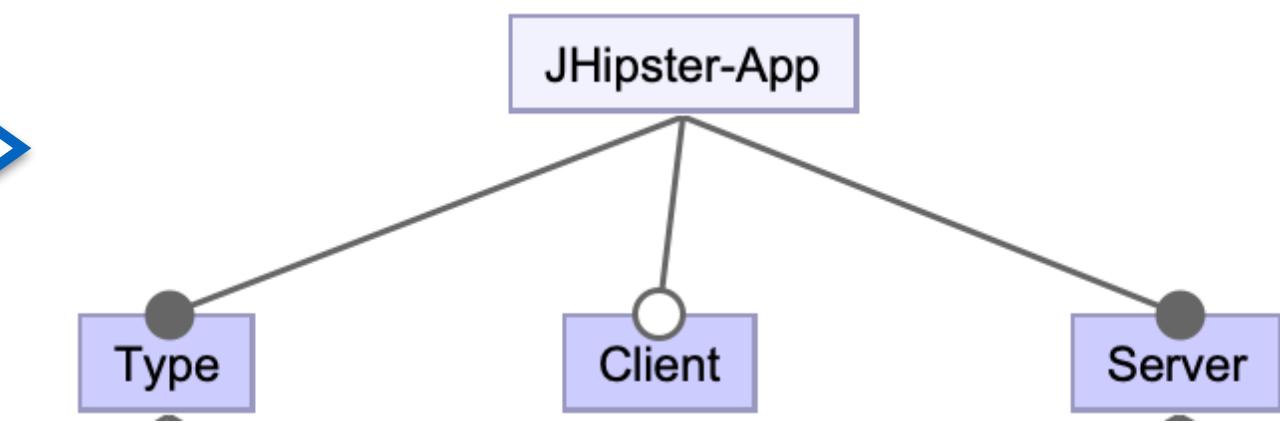

Besides JUnit and Jest, which testing frameworks would you like to use?

- Gatling
- Cucumber
- Protractor

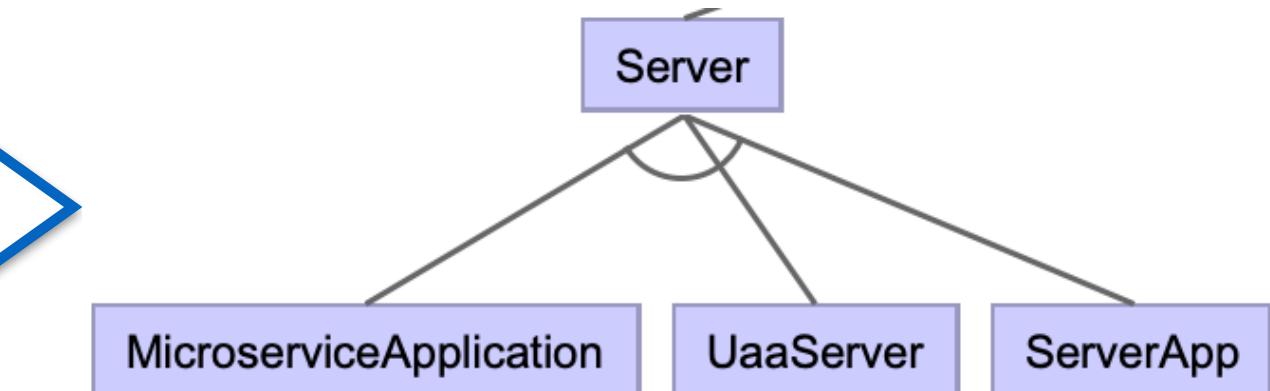

Would you like to enable internationalization support?

- Yes
- No

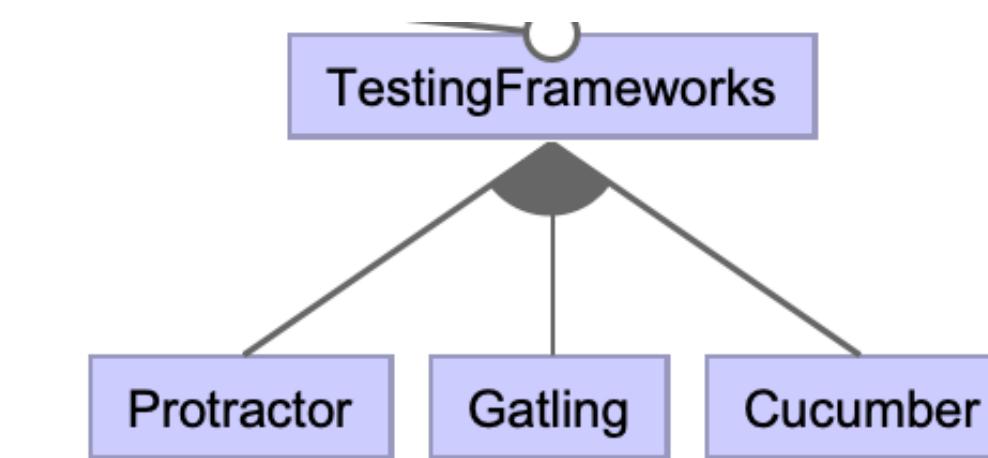

AND decomposition

XOR decomposition

OR decomposition

Optional feature

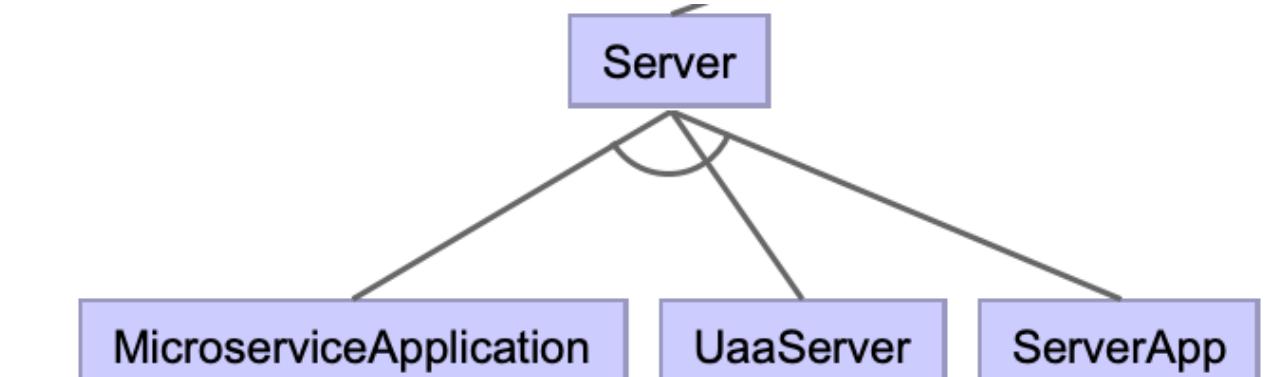

Source: Documentation

Which type of application would you like to create?

You can either use:

- Monolithic application [...]
- Microservice application [...]
- Microservice gateway [...]

XOR decomposition

Which type of database would you like to use?

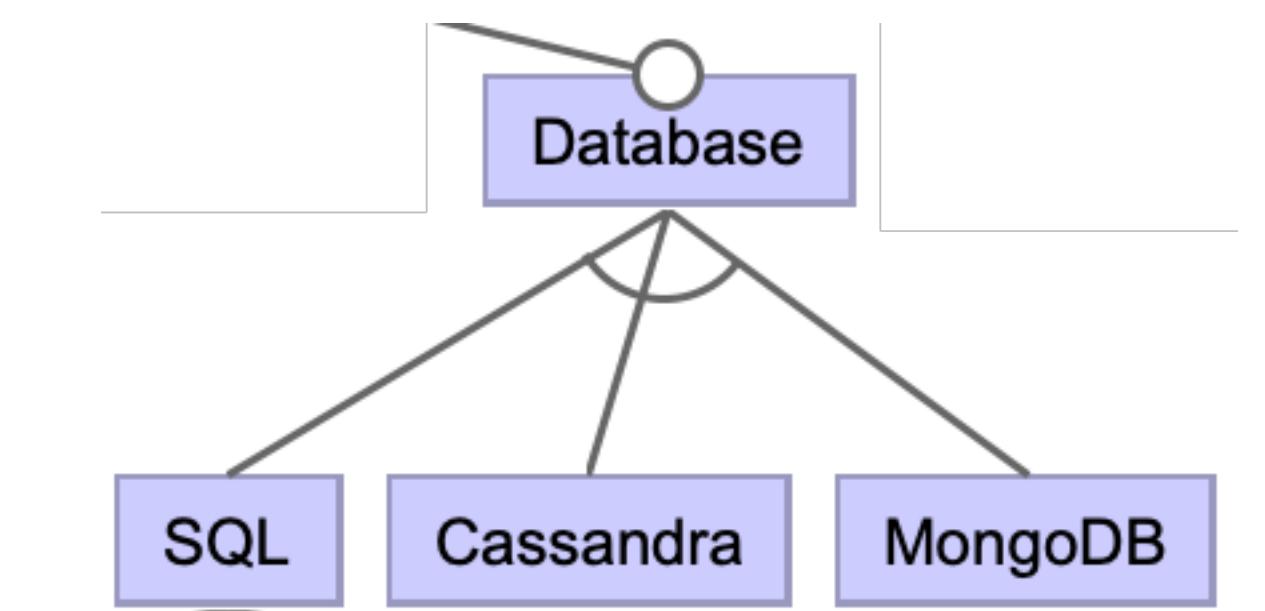

You can choose between:

- No database (only available when using a microservice application)
- An SQL database (H2, MySQL, MariaDB, PostgreSQL, MySQL, Oracle), which you will access with Spring Data JPA
- MongoDB
- Cassandra

Optional feature

XOR decomposition

Additional constraints

$\neg Database \Rightarrow MicroserviceApplication$

$SQL \Rightarrow SpringDataJPA$

Social login (Google, Facebook, Twitter)

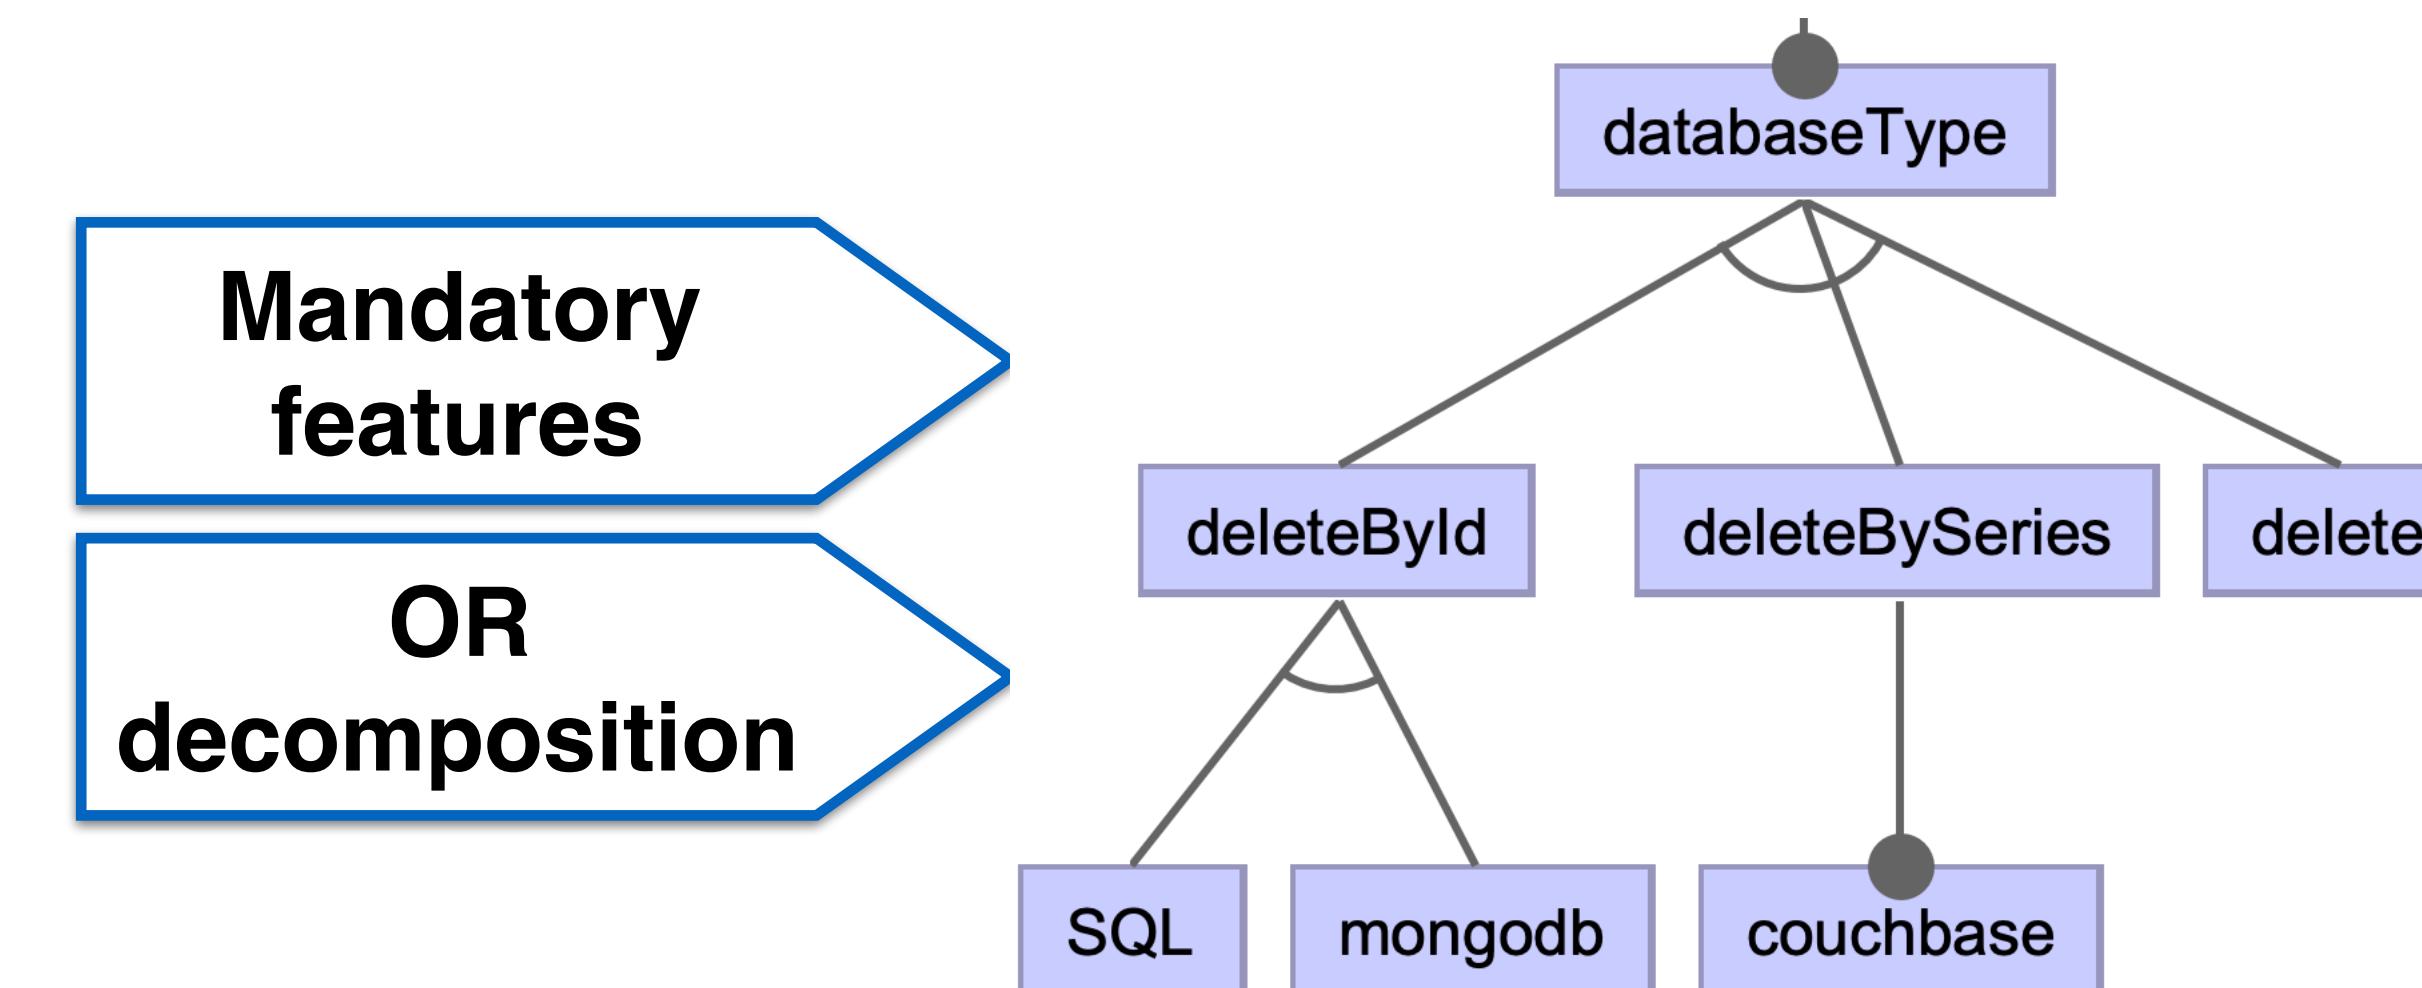

This option is only available if you selected an SQL or MongoDB database.

Additional constraints

$SocialLogin \Rightarrow (SQL \vee MongoDB)$

Variability Binding Time

Variability offers choices.

When we derive a product, we make **decisions**; we decide which features will be included in the product or not. We also say that we **bind** a decision.

Design-time binding

- Clone and own

Compile-time Binding

- Decided before or at compile time
- Allows **optimisations**
 - Removes unnecessary code from the product
- Once the product has been generated and deployed, it is **not variable any more**

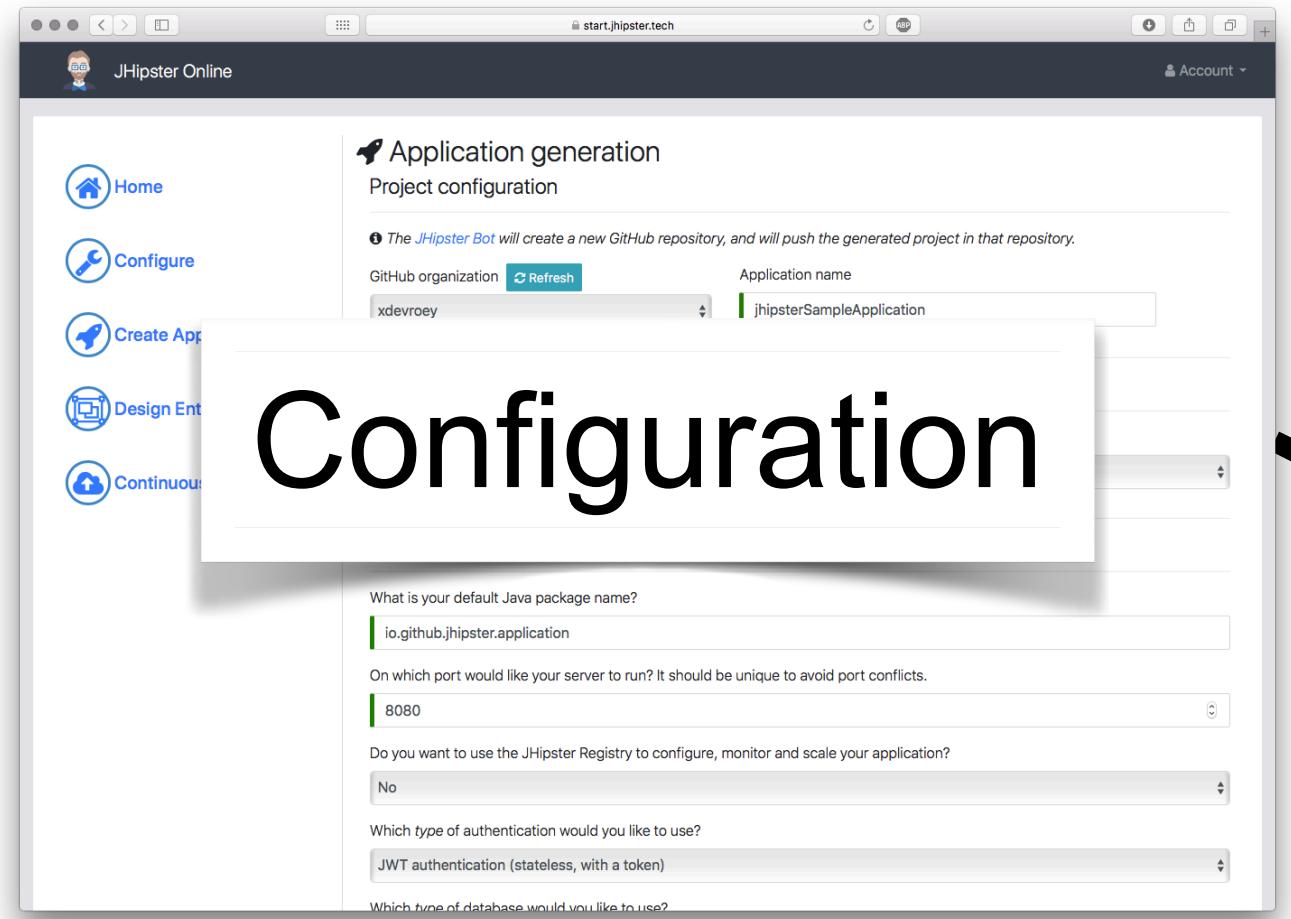

Conditional compiling

- Implements variability with **preprocessors**
- Using **annotated** code (here, templates)

```
<%_ if (databaseType === 'mongodb' || databaseType === 'couchbase') { %>←  
<dependency>  
  <groupId>org.springframework.boot</groupId>  
  <artifactId>spring-boot-starter-data-<%=databaseType%></artifactId>←  
</dependency>  
<%_ } %>  
<dependency>  
  <groupId>org.springframework.boot</groupId>  
  <artifactId>spring-boot-starter-logging</artifactId>  
</dependency>  
  
<% if (databaseType === 'sql') { %>/**  
 * Spring Data JPA repository for the Authority entity.  
 */<% } %><% if (databaseType === 'mongodb') { %>/**  
 * Spring Data MongoDB repository for the Authority entity.  
 */<% } %><% if (databaseType === 'couchbase') { %>/**  
 * Spring Data Couchbase repository for the Authority entity.  
 */<% } %>  
public interface AuthorityRepository extends <% if (databaseType === 'sql') {  
%>JpaRepository<% } %><% if (databaseType === 'mongodb') { %>MongoRepository<% } %><%  
if (databaseType === 'couchbase') { %>N1qlCouchbaseRepository<% } %><Authority, String>  
{  
}
```

Conditional compiling

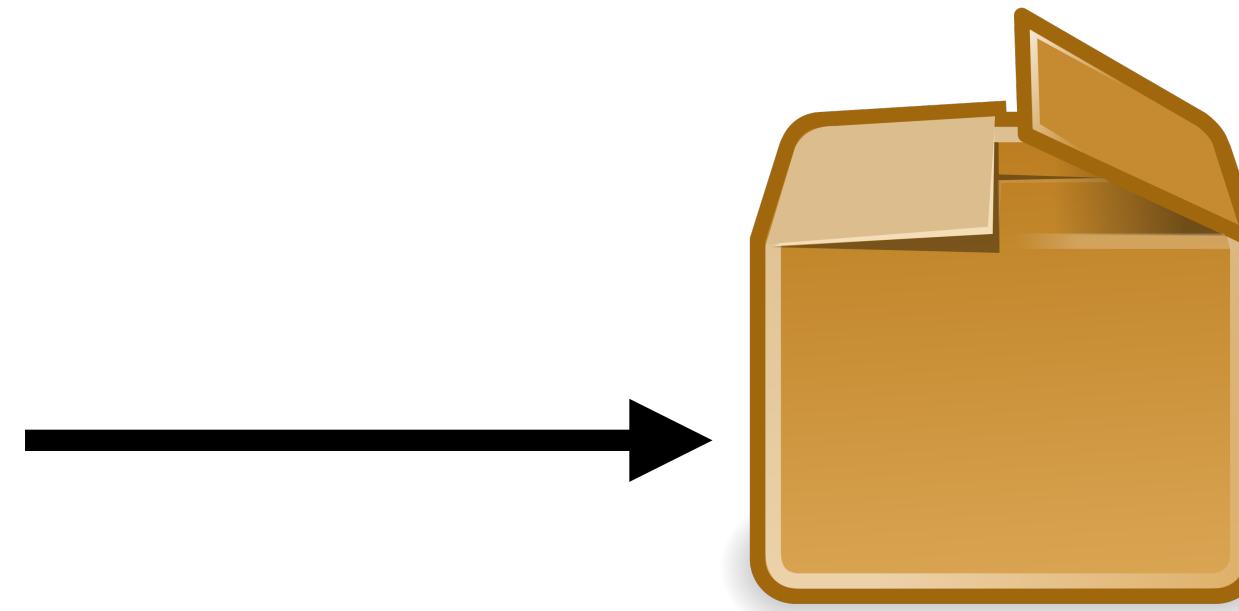

Yeoman

The screenshot shows annotated code with conditional compilation blocks. It includes sections for dependency management and repository interfaces, both of which are conditionally included based on the chosen database type (MongoDB or Couchbase). A large callout box labeled "Annotated code" points to this section.

```
<%_ if (databaseType === 'mongodb' || databaseType === 'couchbase') { %>
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-data-<%=databaseType%></artifactId>
</dependency>
<% } %>
<dependency>
  <groupId>com.novocode</groupId>
  <artifactId>jdbi</artifactId>
</dependency>
<% if (databaseType === 'couchbase') { %>/*

 */<% } %>
<% if (databaseType === 'mongodb') { %>/*
 * Spring Data MongoDB repository for the Authority entity.
 */<% } %>
public interface AuthorityRepository extends <% if (databaseType === 'sql') {
  >JpaRepository<% } %><% if (databaseType === 'mongodb') { %>MongoRepository<% } %><%
if (databaseType === 'couchbase') { %>N1qlCouchbaseRepository<% } %><Authority, String>
{
}
```

Annotated code

JHipster

Load-time Binding

- Decided after compilation when the program is started
- More flexibility for **reconfiguration**
 - ... but Requires a reboot
- Memory and performance **overhead**
 - All variations are compiled into a single binary
 - Consistency conditions must be checked at load time
 - Unnecessary functionality may be considered as potential **security threat**

Parameters and Configuration Files

- Implement variability using conditional statements (such as if and switch)
- Controlled by configuration parameters
 - Passed to the method or module,
 - Set as global variables in a system

Gcc

```
/* Enable -Werror=coverage-mismatch when -Werror and -Wno-error
   have not been set. */
if (!global_options_set.x_warnings_are_errors
    && warn_coverage_mismatch
    && (global_dc->classify_diagnostic[OPT_Wcoverage_mismatch] ==
         DK_UNSPECIFIED))
  diagnostic_classify_diagnostic (global_dc, OPT_Wcoverage_mismatch,
                                 DK_ERROR, UNKNOWN_LOCATION);

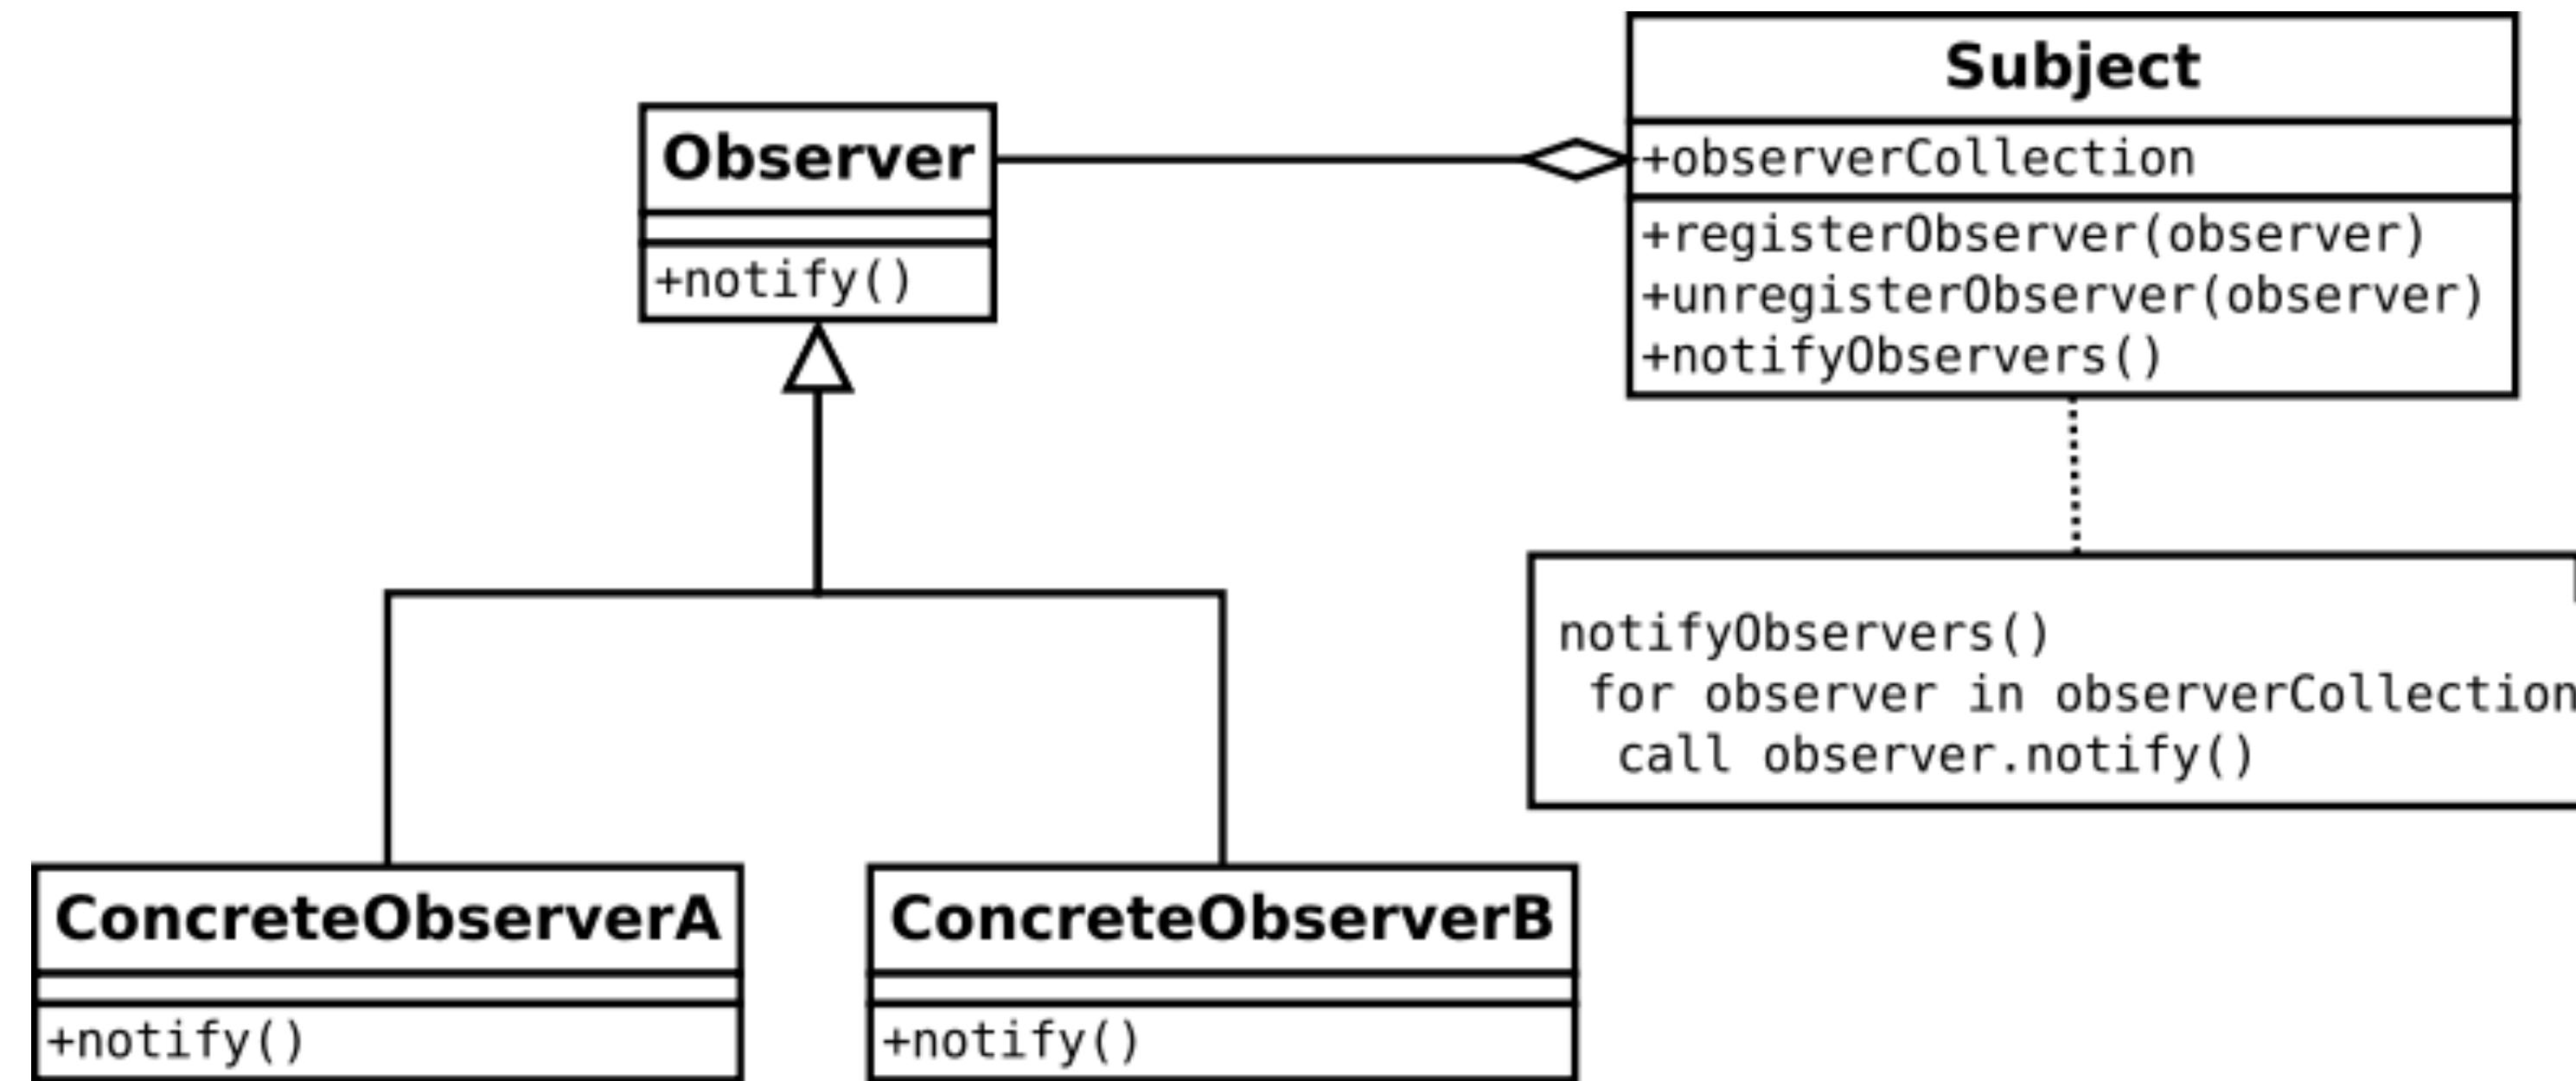

/* Save the current optimization options. */
optimization_default_node = build_optimization_node (&global_options);
optimization_current_node = optimization_default_node;
```

Run-time Binding

- Decided during program execution and may be changed latter
 - Used in dynamic adaptive systems (e.g., robots)
- Most flexible to **reconfigure**
 - Able to react to internal and external stimuli by adapting its behaviour
- Memory and performance **overhead**
 - All variations are compiled into a single binary
 - Consistency conditions must be checked at run time
- Unnecessary functionality may be considered as potential **security threat**

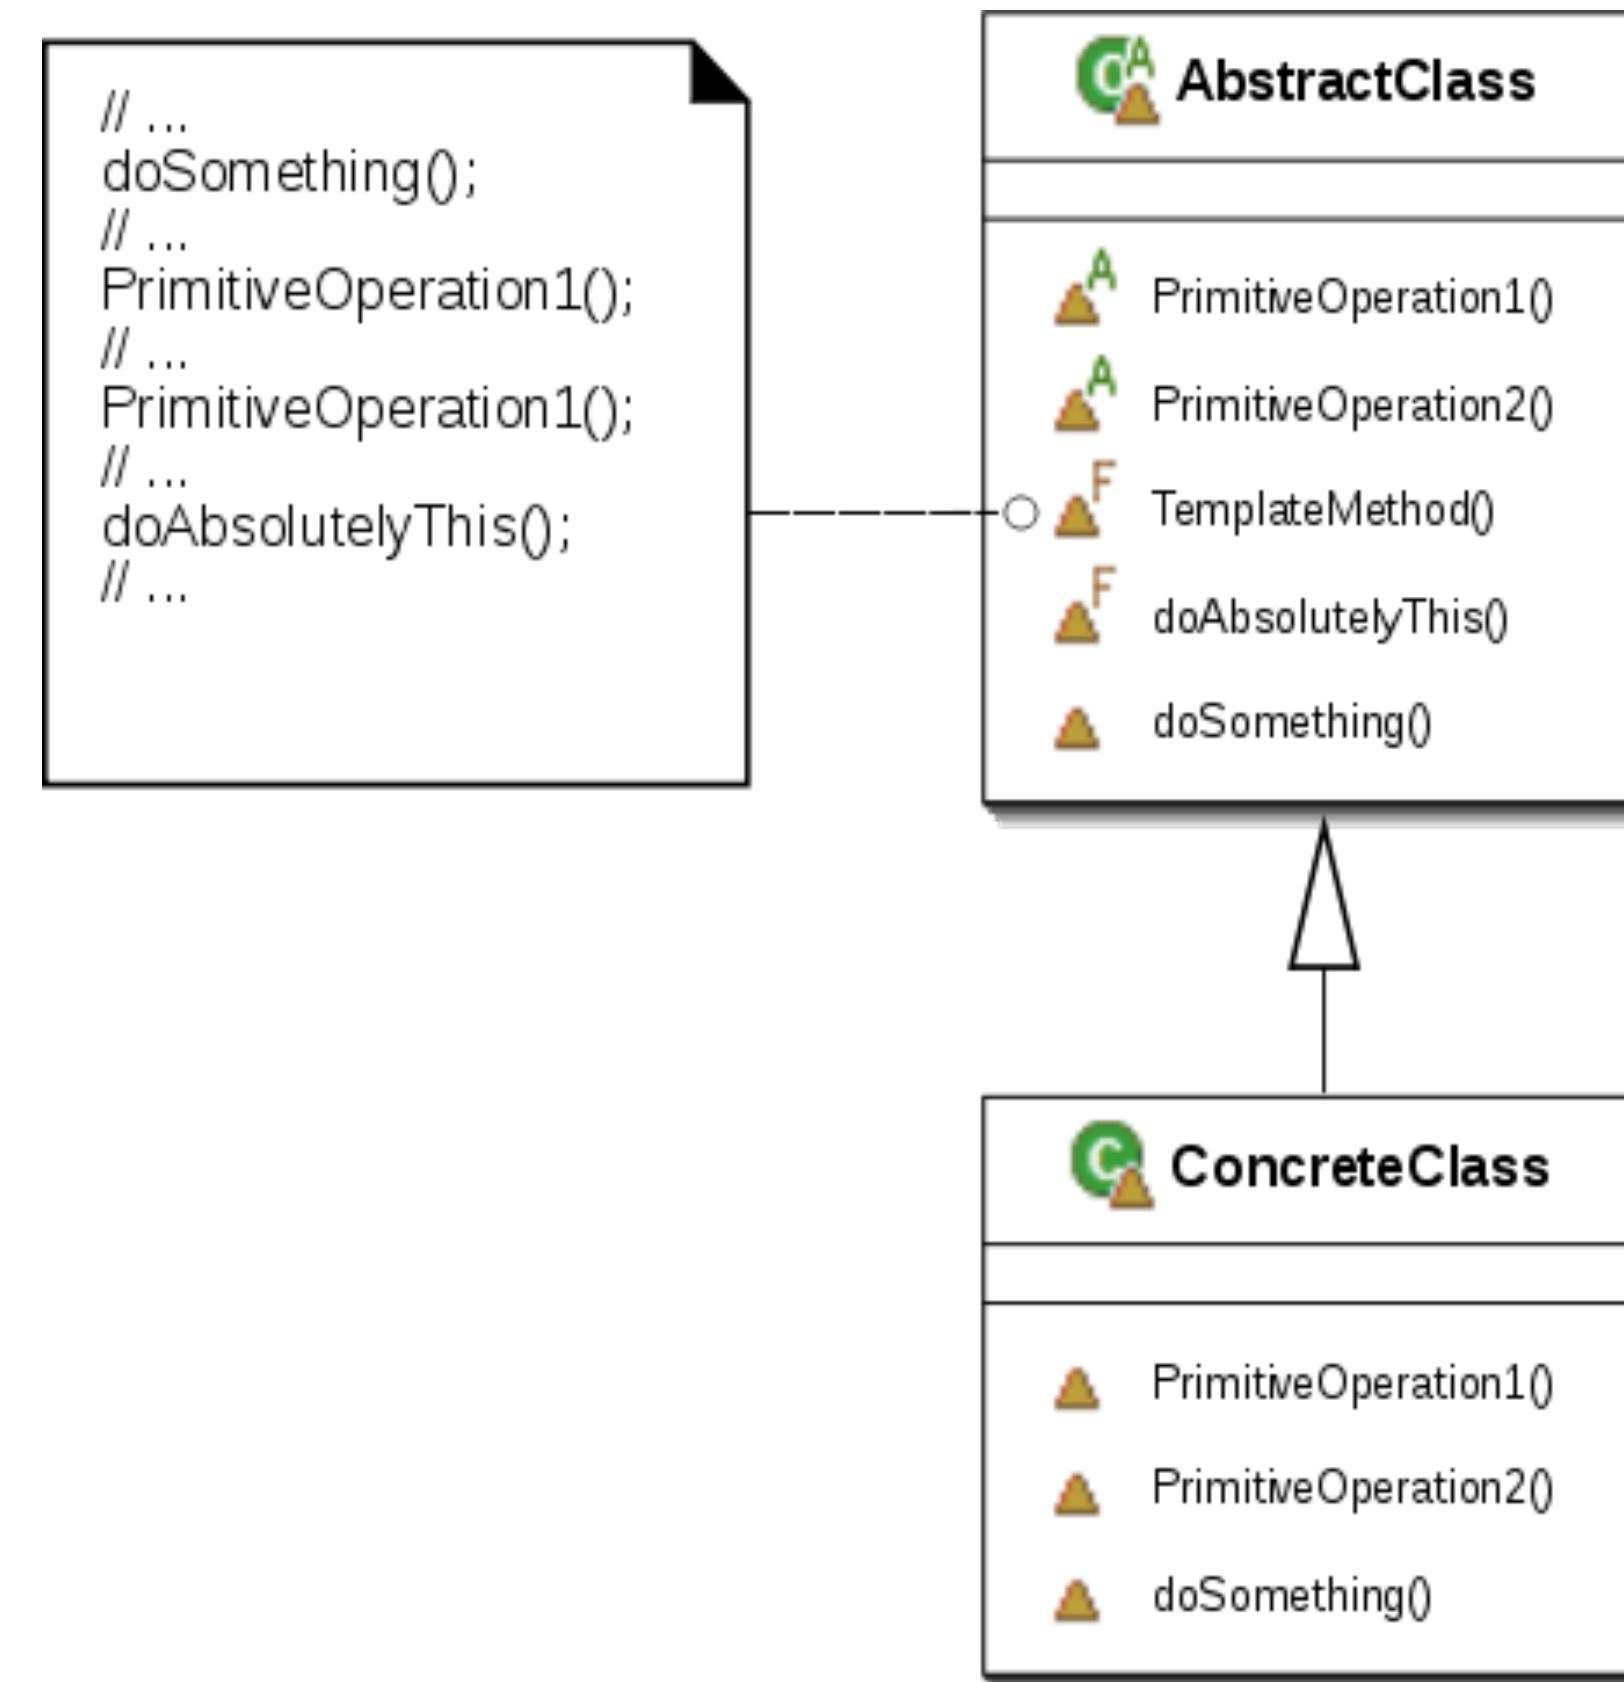

Design Patterns

- Observer pattern (publish/subscribe) to implement distributed event handling
 - Features are implemented as observers
 - Variability is achieved by registering or not registering observers

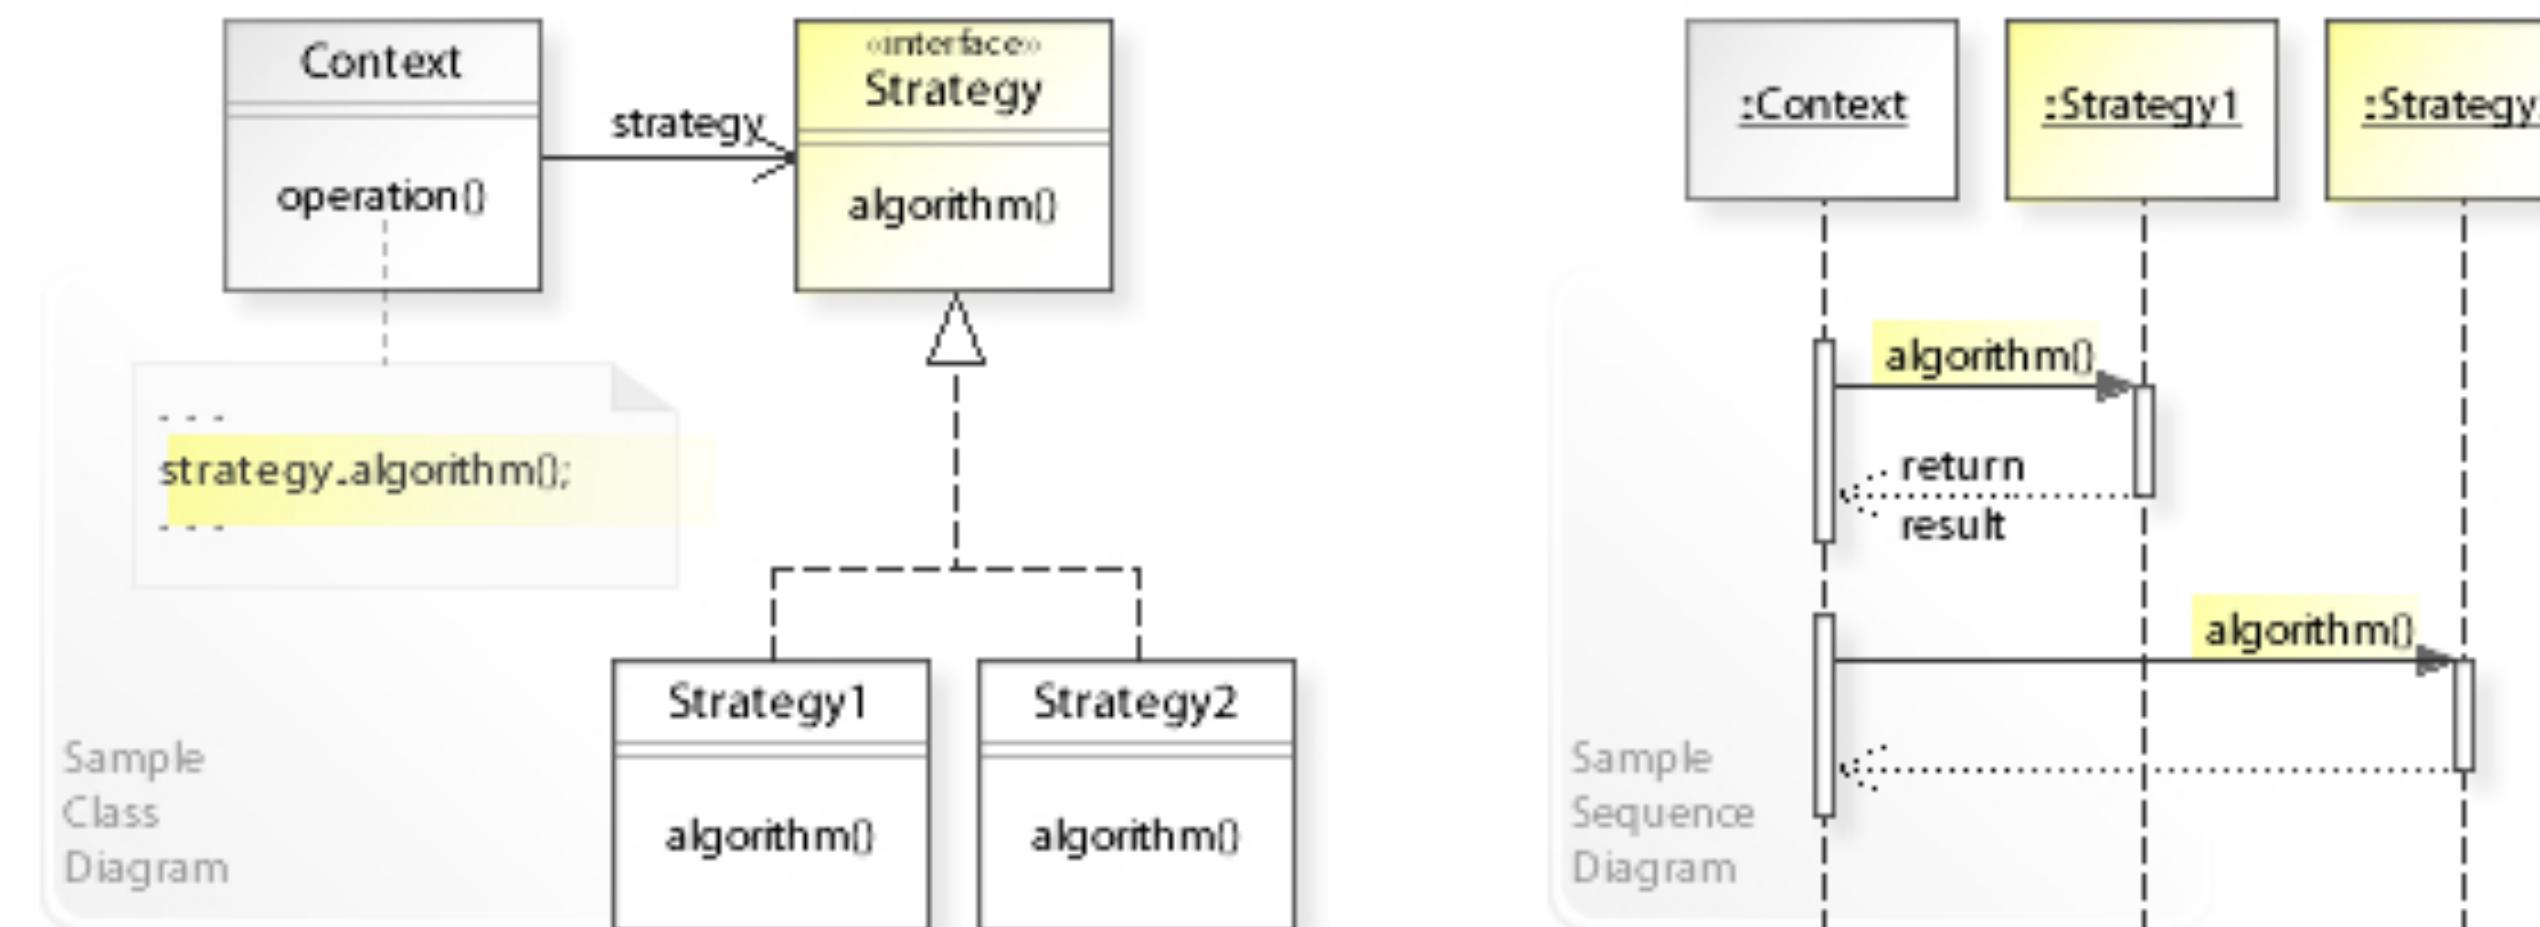

Design Patterns

- Template-method pattern
 - Using an abstract class
 - Implement feature's behaviour using inheritance

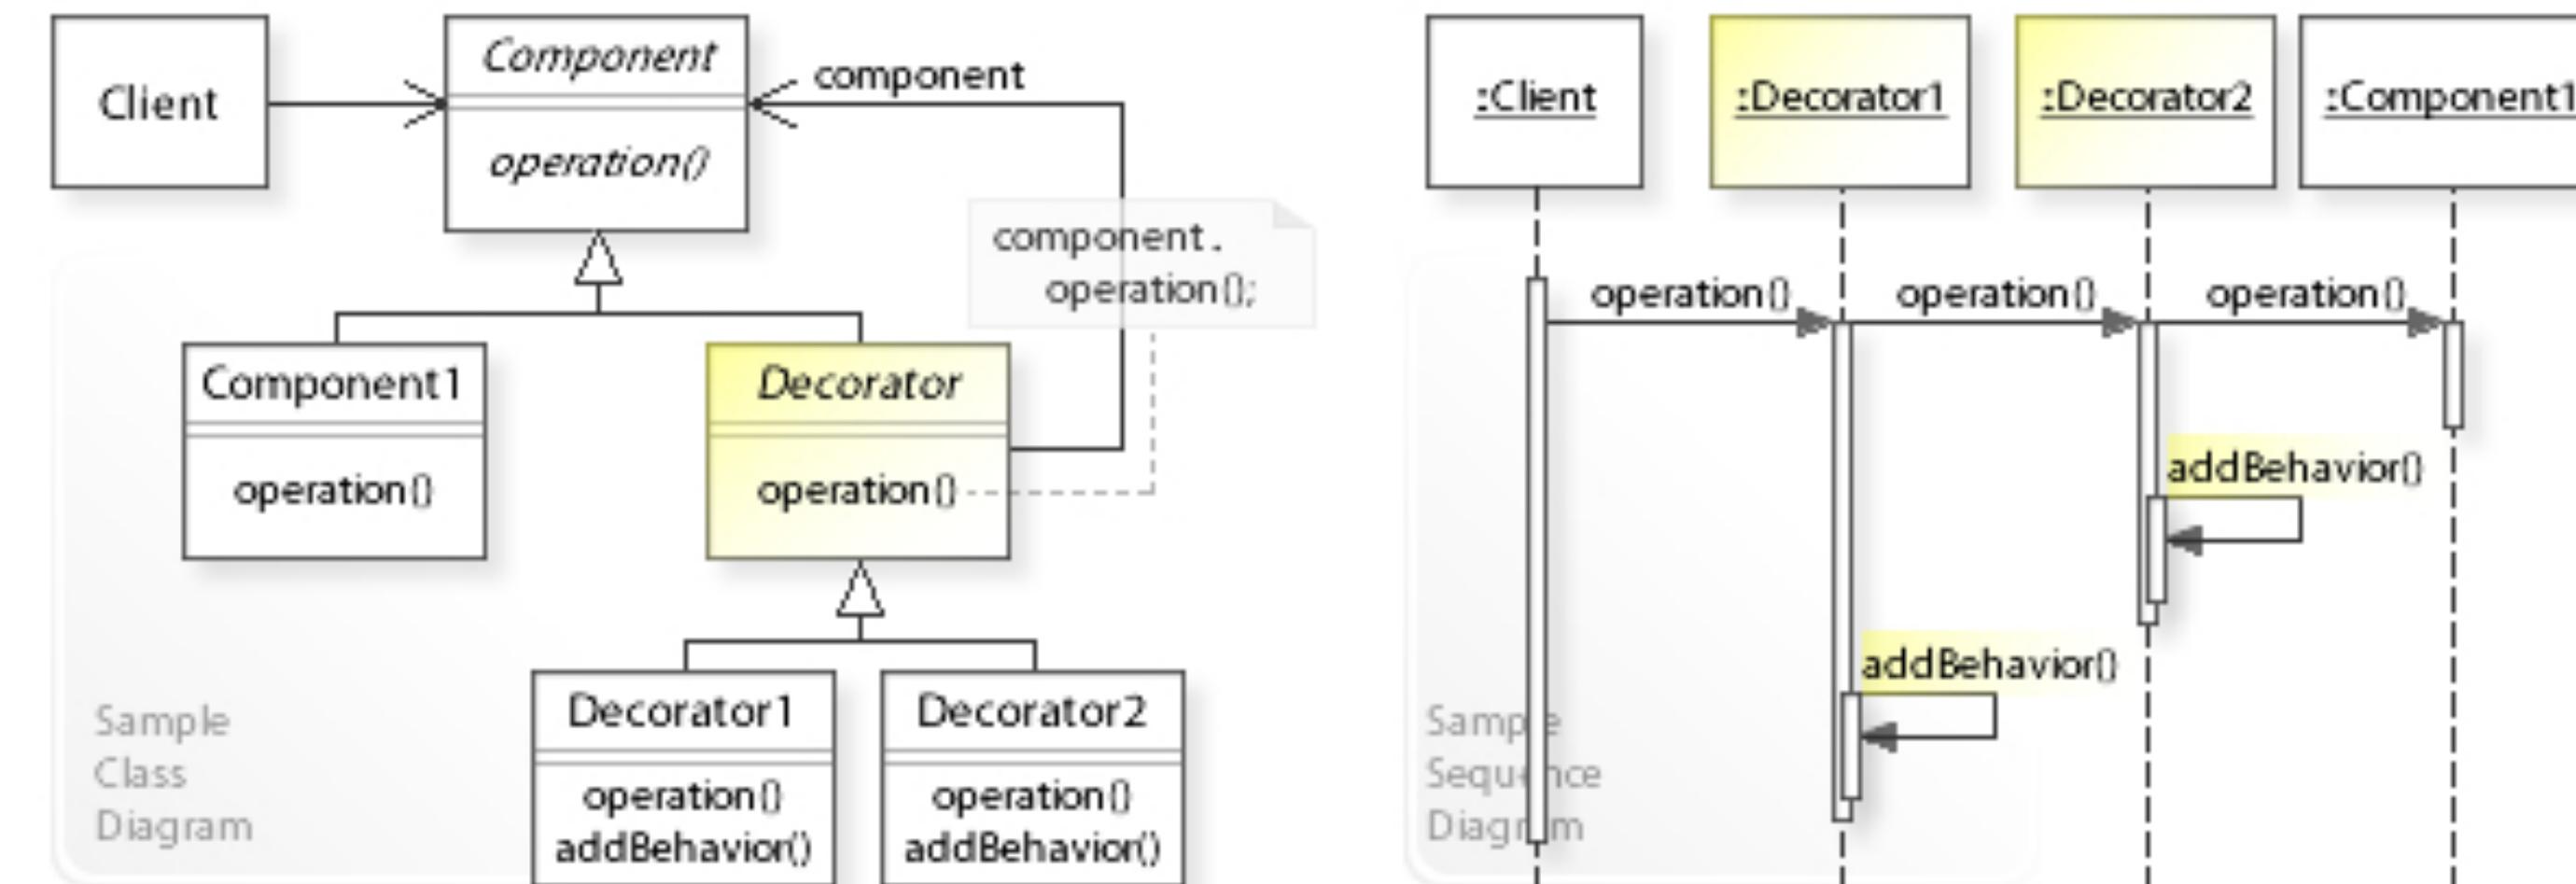

Design Patterns

- Strategy pattern
 - Encodes a callback mechanism
 - Alternative features where each corresponds to one implementation of the algorithm
 - Uses polymorphism instead of conditional statements

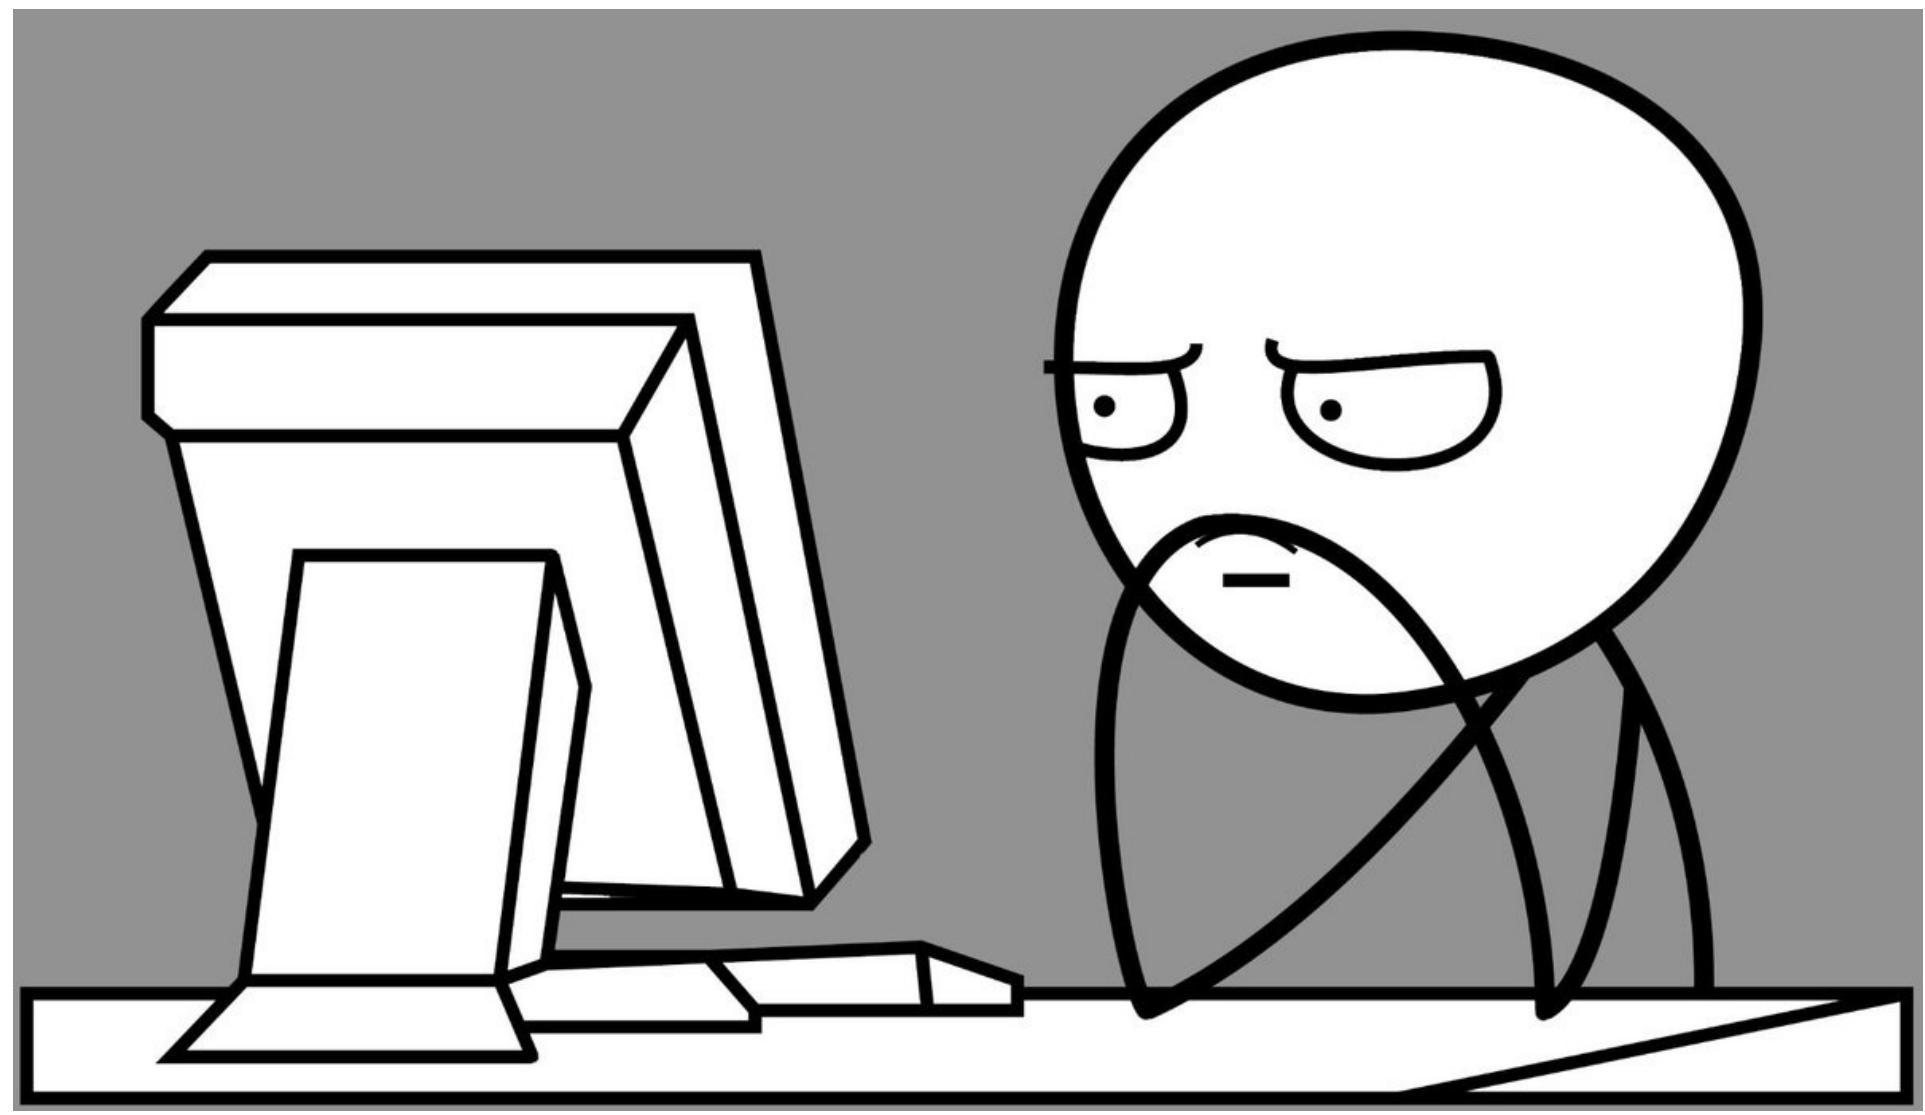

Design Patterns

- Decorator pattern
 - Extends object with additional behaviour at run time
 - Optional features and feature groups, of which multiple features can be selected, are implemented as decorators

Variability Binding Time

- **Design-time**
 - Clone and own
- **Compile-time**
 - Conditional compilation
- **Load-time**
 - Program parameters and configuration files
- **Run-time**
 - Design patterns

Take-aways

- Variability enables **adaptability** to the business domain
 - It should be **planned** and **managed**
 - Identify development **practices**
 - Clone and own
 - Software product line
 - Most probably something intermediate
 - Binding
 - Design, compile, load, and/or runtime binding
 - Variability implementation mechanism(s) (conditional compiling, parameters, design patterns)
 - **Feature modelling** helps to manage variability
 - Analysis on the feature model
 - Sample products to test
